## ABSTRACT

Let $X$ be a compact connected Riemann surface of genus $g$ and let $f: X \rightarrow \mathbb{P}^{1}$ be a meromorphic function of degree $n$. Classes of such covers are in one to one correspondence with the primitive systems, which are tuples of elements $\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ in the symmetric group $S_{n}$ taken up to conjugation and the action of the braid group, such that $x_{1} \cdot x_{2} \cdots \cdots x_{r}=1$ and $G=\left\langle x_{1}, x_{2}, \cdots, x_{r}\right\rangle$ is a primitive subgroup $G$ of $S_{n}$. This thesis is a contribution to the classification of primitive genus $g \leqslant 2$ systems of sporadic almost simple groups.

## ACKNOWLEDGEMENTS

I am very thankful to the creator of the universe, the Almighty, and the Merciful for His blessing given during this PhD study. I express my deepest gratitude to my supervisors, Dr. Kay Magaard and Professor Sergey Shpectorov for giving the PhD project. Without their continuing support and guidance, the work presented here may never have been accomplished. I would like to acknowledge the Kurdistan regional government for awarding me a scholarship to pursue the PhD degree in the UK.

My special Thanks go to my Kurdish friends at the University of Birmingham, specially, Dr.Rashad Lak, Dr.Sanhan M.Khasraw, Dr.Kawa M.Manmi, and Dr.Haval M. Mohammed.

Finally, I am deeply indebted to my family for their everlasting encouragement, and all their financial support especially after my sponsor was no longer able to continue funding my study.

## CHAPTER 1

## InTRODUCTION

A connected second countable Hausdorff topological space $X$ together with a complex structure is called a Riemann surface[27]. In other words, a Riemann surface is a one-dimensional complex manifold. Topologically, compact Riemann surfaces are homeomorphic to a sphere, a torus, or a finite number of tori joined together. The genus $g$ of a compact Riemann surface $X$ is defined to be number of tori which are joined together. Let $f: X \rightarrow \mathbb{P}^{1}$ be meromorphic function, that is, a holomorphic mapping from $X$ to the Riemann sphere $\mathbb{P}^{1}$. The meromorphic function $f$ is of degree $n$ if the fiber $f^{-1}(p)$ for general $p \in \mathbb{P}^{1}$ is size $n$. A point $a \in \mathbb{P}^{1}$ is a branch point if $\left|f^{-1}(a)\right|<n$. Every meromorphic function $f$ has finitely many branch points. Let $B=\left\{a_{1}, a_{2}, \cdots, a_{r}\right\}$ be the set of branch points of $f$ and let $a_{0} \in \mathbb{P}^{1} \backslash B$. Denote by $\Pi_{1}=\pi_{1}\left(\mathbb{P}^{1} \backslash B, a_{0}\right)$, the fundamental group of $\mathbb{P}^{1} \backslash B$ with the base point $a_{0}$. Let $\gamma_{i} \in \pi_{1}\left(\mathbb{P}^{\mathbf{1}} \backslash B, a_{0}\right)$ be corresponding to the path winding once around point $a_{i}$ in the counter clockwise direction and not around any other branch points. The fundamental group $\Pi_{1}$ is generated by the homotopy classes of the closed paths $\gamma_{i}$. The homotopy lifting of paths induces an action on the fundamental group $\Pi_{1}$ on the fiber $f^{-1}\left(a_{0}\right)$ (see Section 2.1). This action gives us a homomorphism $\varphi_{f}$ from the fundamental group $\Pi_{1}$ to the symmetric group $S_{n}$. The connectedness of the Riemann surface $X$ yields that $\varphi_{f}\left(\Pi_{1}\right)$ is a transitive subgroup of $S_{n}$ and this group is called the monodromy group of the ramified cover $f: X \rightarrow \mathbb{P}^{1}$ and is denoted by $\operatorname{Mon}(X, f)$. The generators $\left\{\gamma_{1}, \ldots, \gamma_{r}\right\}$ satisfy the relation $\gamma_{1} \cdot \gamma_{2} \cdot \ldots \cdot \gamma_{r}=1$ and they are distinguished generators of the fundamental group $\Pi_{1}$. Thus the generators of the monodromy group $\left\{g_{1}, \ldots, g_{r}\right\}$ where
$g_{i}=\varphi_{f}\left(\gamma_{i}\right)$ will satisfy the same relation. Furthermore, the following statements are satisfied:

$$
\begin{gather*}
G=\left\langle g_{1}, \ldots, g_{r}\right\rangle  \tag{1}\\
g_{1} \cdots g_{r}=1,  \tag{2}\\
\sum_{i=1}^{r} i n d g_{i}=2(n+g-1) \tag{3}
\end{gather*}
$$

Equation 3 is called Riemann Hurwitz formula. Here $\operatorname{ind} g_{i}=n$-number of orbits of $\left(g_{i}\right)$ on $f^{-1}\left(a_{0}\right)$. Let $G=\operatorname{Mon}(X, f)$ and let $C_{i}=g_{i}^{G}$ be the conjugacy classes of $G$ containing $g_{i}$. Then the set $C=\left\{C_{1}, \ldots, C_{r}\right\}$ is the ramification type of $f$. In our study, we look at the set

$$
N(C)=\left\{\left(g_{1}, \ldots, g_{r}\right): G=\left\langle g_{1}, \ldots, g_{r}\right\rangle, g_{i} \cdots g_{r}=1 \text { and } g_{i} \in C_{i} \text { for all } \mathrm{i}\right\}
$$

which is equivalent to the set of all monodromy homeomorphism and we call the elements of $N(C)$ Nielsen tuples. Let $G$ be a transitive group of $S_{n}$. A genus $g$-system is a tuple $\left(g_{1}, \ldots, g_{r}\right)$ satisfying (1), (2) and (3). If $G$ acts primitively, then the genus $g$ system is called a primitive genus g system.

We are more interested in when the meromorphic function $f$ is indecomposable, that is, $f$ can not written of the form $f=f_{1} \circ f_{2}$ where degree of $f_{1}$ and $f_{2}$ more than one. Which yields the monodromy group $\operatorname{Mon}(X, f)$ acts primitively on fiber.

A natural question is : Which finite groups can be the monodromy groups $\operatorname{Mon}(X, f)$ for a fixed genus of $X$ ?

In 1990, Guralnick and Thompson [15] put forward the following conjecture: For any fixed non-negative integer $g$, there is a finite set $\mathscr{E}(g)$ of simple groups such that if $X$ is a compact Riemann surfaces of genus $g$ and $f: X \rightarrow \mathbb{P}^{1}$ is a meromorphic function, then the non-abelian composition factors of the mononodromy group $\operatorname{Mon}(X, f)$ are either alternating groups or members of $\mathscr{E}(g)$. This conjecture was established by Frohardt, Magaard [13]. As $\mathscr{E}(g)$ is finite, one would like to determine $\mathscr{E}(0), \mathscr{E}(1)$ and $\mathscr{E}(2)$ explicitly. Moreover, it would be useful for future applications to determine all possibilities of how a group in $\mathscr{E}(g)$ can arise, as explic-
itly as possible. Let $\mathscr{E}(g)^{*}=\left(\bigcup_{(X, f)} c f(\operatorname{Mon}(X, f))\right)$, it is well known that for all $X$, all prime $p$ and all $n>4, C_{p} \in \mathscr{E}(g)^{*}$ and $A_{n} \in \mathscr{E}(g)^{*}$. Indeed for each $G$ which is either a $C_{p}$ or $A_{n}$, there is a cover $\psi: \mathbb{P}^{1} \rightarrow \mathbb{P}^{1}$ depending on $G$ such that $\operatorname{Mon}(X, f) \cong G$ (see [33, p.17]). We call a group a genus $g$-group if $G=\operatorname{Mon}(X, f)$ for some $(X, f)$ and $g(X)=g$.

Using Riemann's Existence Theorem, Guralnick and Thompson showed in [15] that the elements $\mathscr{E}(g)$ occur in a primitive monodromy action, i.e if $G \in \mathscr{E}(g)$, then $\exists(X, f)$ such that $G=$ $\operatorname{Mon}(X, f)$ and $G$ acts primitively on $f^{-1}\left(a_{0}\right)$. This fact brings the Theorem of Aschbacher and Scott into the picture.

The Fitting subgroup of the group $G$ is denoted by $F(G)$ and it is defined to be the product of all nilpotent normal subgroups of the group $G$. It is the largest nilpotent normal subgroup of the group $G$. If a group $H$ is perfect and $H / Z(H)$ is simple, then $H$ is called a quasisimple. A subgroup $H$ of the group $G$ is called a component of $G$ if $H$ is a quasisimple subnormal subgroup of $G$. Moreover, $F^{*}(G)=F(G) E(G)$ is called general Fitting subgroup of the group $G$, where $E(G)$ is product of all components of $G$. Now, with these definitions we can formulate the important result of Aschbacher and Scott [1].

Theorem 1.0.1 (Aschbacher and Scott). Let $G$ be a finite group and $K$ is a maximal subgroup of $G$ such that $\cap_{g \in G} K^{g}=\{1\}$. Let $P$ be a minimal normal subgroup of $G$ and $S$ be a minimal normal subgroup of $P$. Let $\Delta=\left\{S_{1}, \cdots, S_{t}\right\}$ be the set of $G$ conjugates of $S$. Then $G=K P$ and exactly one of the following holds:

1. $S$ of prime order
2. $F^{*}(G)=P \times R$ where $P \cong R$ and $K \cap P=\{1\}$
3. $F^{*}(G)=P$ is non-abelian, $K \cap P=\{1\}$
4. $F^{*}(G)=P$ is non-abelian, $K \cap P \neq\{1\}=K \cap S$
5. $F^{*}(G)=P$ and $K \cap P=K_{1} \times \cdots \times K_{t}$ where $K_{i}=K \cap S_{i} \neq\{1\}, 1 \leqslant i \leqslant t$.

Shih [34] and Guralnick and Thompson [15] proved that there is no primitive genus zero systems in case 2 and 3 respectively of the Theorem 1.0.1. Aschbacher [2] studied case 4 and he showed that the general Fitting subgroup of $G$ must be equal to $A_{5} \times A_{5}$ in case of a genus zero system. case 5 was considered by Frohardt, Guralnick and Magaard [10] when $S_{i}$ is of Lie
type of rank 1 . They proved that $t \leqslant 2$. Furthermore, they established that $\left[S_{i}: K\right] \leqslant 10000$, when $S_{i} / K_{i}$ is point action, $t=1$ and $S_{i}$ is a classical group. It follows from this result and the results of Frohardt, Guralnick and Magaard [14] that once the actions of $\left[S_{i}: K\right] \leqslant 10000$, if $S_{i}$ is a classical and $t=1$. The first case of the Theorem 1.0.1 is the affine case when $F^{*}(G)$ is abelian group. It was first was considered by Guralnick and Thompson[15]. They proved that there are only finitely many primitive affine groups which are primitive group of genus zero and Neubauer in [32] studied and extended result to the genus one and two case. The analysis of the affine genus zero case was completed by Magaard, Shpectorov and Wang[25] they give a complete list of the primitive affine genus zero systems.In his PhD thesis Salih classified the affine primitive genus one and two systems[31]. In this thesis we are interested in final case of the Theorem 1.0.1. Our goal to determine all primitive genus zero, one and two systems for the almost simple groups $G$ where $F^{*}(G)$ is a simple sporadic group.

We now briefly outline the contents of the thesis. In Chapter 2 we review some basic background. This chapter is divided into five sections. In the first section we start with some basics in algebraic topology and collect facts on covering spaces and fundamental groups. As well, we introduce monodromy groups. Section two is devoted to the Riemann surfaces. we discuss the Riemann Existence Theorem, review the connections between the coverings of a Riemann surface and permutation groups. In section three we study the Hurwitz space $H_{r}^{A}(G)$ which is the moduli space of $G$-covers of the Riemann sphere $\mathbb{P}^{1}$, where $\operatorname{Inn}(G) \leqslant A \leqslant A u t(G)$ and $r$ is the number of branch points. If $A=\operatorname{Inn}(G)$, we denote the Hurwitz space $H_{r}(G)^{A}$ by $H_{r}^{i n}(G)$. We focus on the subset $H_{r}^{i n}(C)$ of Hurwitz space $H_{r}^{i n}(G)$, where $C$ is a fixed ramification type.

Next we define Nielsen tuples. The base space $O_{r}$ called configuration space, the space of branch point of $f$ of cardinality r , is a topological space over $\mathbb{C}$. The Hurwitz space $H_{r}^{A}(G)$ is an unramified covering space of the base space $O_{r}$. As is well known, the fundamental group of the space $O_{r}$ is the Artin braid group on r strands which is denoted by $B_{r}$. The braid group possesses the well known presentation on $r-1$ generators $\left\{Q_{1}, \cdots, Q_{r-1}\right\}$ satisfying the following relations

$$
\begin{equation*}
Q_{i} Q_{i+1} Q_{i}=Q_{i+1} Q_{i} Q_{i+1} \text { for all } i<r-1 \tag{4}
\end{equation*}
$$

and

$$
\begin{equation*}
Q_{i} Q_{j}=Q_{j} Q_{i} \text { for all } i, j=1,2, \cdots r-1 \text { with }|i-j| \geqslant 1 \tag{5}
\end{equation*}
$$

The group action of the braid group $B_{r}$ on the fibers completely determines the connected components of Hurwitz space $H_{r}^{A}(G)$. In particular, the fiber of the subspace $H_{r}^{\text {in }}(C)$ of the Hurwitz space $H_{r}^{i n}(G)$ are parametrized by the set $N(C)$ and the subgroup of the braid group that preserves the order of ramification type $C$ which is defined by parabolic subgroup $B$. Thus the connected components $H_{r}^{i n}(C)$ are parametrized by the $B$-orbits on the Nielsen classes $N(C)$.

Section four is devoted to describing primitive permutation groups. In the final section of this chapter we review general criteria for determining possible signatures. Our main results, Lemma 2.5.18, Lemma 2.5.19 and Lemma 2.5.20, give the complete classification of genus zero, one and two systems for all class of maximal subgroups of the group $G$ of large index. Moreover, these lemmas together with Lemma 2.5.17 help us to prove that some sporadic simple groups are not genus zero, one and two groups.

Chapter 3 is divided into eleven sections. In the first section we explain some criteria to eliminate ramification types of sporadic simple groups. Section two, three, four and five devoted to ramification types of Mathieu groups, Janko groups, Conway groups and Higman-Sim groups, respectively, by using series of filters to reduce the set of possible ramification types. For instance, we show that the groups $J_{3}, J_{4}, C o_{2}$ and $C o_{1}$ possesses no primitive genus zero, one and two systems.

Now we will state the following Theorem:
Theorem 1.0.2. Let $G$ be an almost simple group with $F^{*}(G)$ a sporadic simple group and $f: X \rightarrow \mathbb{P}^{1}$ be a meromorphic function where $X$ is a compact Riemann surface of genus zero, one or two. Then $G$ is a composition factor of $\operatorname{Mon}(X, f)$ if and only if $G$ isomorphic to the group $M_{11}, M_{12}, M_{12}: 2, M_{22}, M_{22}: 2, M_{23}, M_{24}, J_{1}, J_{2}, J_{2}: 2, C_{3}, H S$, or $H S: 2$

Theorem 1.0.3. Let $G$ be any one of the groups $J_{3}, J_{4}, C o 2, C o 2: 2, C o o_{1}, M c L, M c L: 2, S u z$, $S u z: 2, H e, H N, H N: 2, F i_{22}, F i_{22}: 2, F i_{23}, F i_{24}, F i_{24}: 2, O N, O N: 2, L y, T h, R u, R u: 2, B$, $M$. Then $G$ possesses no primitive genus zero, one and two systems.

Sections three up to section eleven give a complete proof of Theorem 1.0.3.

Chapter 4 is to provide a complete description of the braid orbits of Nielsen classes of sporadic simple groups. Firstly we present a table with the number of ramification types for each sporadic simple group for which the corresponding Nielsen classes are non-empty. This chapter is devoted to describing the GAP package MAPCIASS. It is used for calculation of braid orbits. The MAPCLASS package is a modernized version of the GAP package BRAID. MAPCLASS has 17 functions. In this thesis we use two of them.

Chapter 5 contains a summary of our work.

Appendix A contains tables representing the results of our computation of primitive genus zero system in sporadic simple groups satisfying Theorem 1.0.2.

Theorem 1.0.4. Let $G$ be a sporadic simple group. Then up to isomorphism, there exists 11 primitive genus zero groups satisfying Theorem 1.0.2. The corresponding primitive genus zero systems are enumerated in the Tables 5.4 to 5.19.

Appendix B contains tables representing the results of our computation of primitive genus one system in sporadic simple groups satisfying Theorem 1.0.2.

Theorem 1.0.5. Let $G$ be a sporadic simple group. Then up to isomorphism, there exists 11 primitive genus one groups satisfying Theorem 1.0.2. The corresponding primitive genus one systems are enumerated in the Tables 5.20 to 5.41.

Appendix C contains tables representing the results of our computation of primitive genus two system in sporadic simple groups satisfying Theorem1.0.2.

Theorem 1.0.6. Let $G$ be a sporadic simple group. Then up to isomorphism, there exists 11 primitive genus two groups satisfying Theorem 1.0.2. The corresponding primitive genus two systems are enumerated in the Tables 5.42 to 5.69.

## CHAPTER 2

## BACKGROUND

In this chapter, we review and cover some background knowledge which will be used throughout this thesis. We will start with a section on algebraic topology to collect the facts on covering space and the fundamental group that we need in the sequel.

### 2.1 Covering and the fundamental group

Definition 2.1.1. Let $X$ be a topological space. A continuous map $f$ from the interval $[0,1]$ to the space $X$ is called a path; $f(0)=x_{0}$ is called the start (initial) point and $f(1)=x_{1}$ is called the end (terminal) point. In addition, if the initial and terminal points of a path are equal, then $f$ is said to be a loop. We say that a loop is based at a point $a_{0}$ if its initial point is $a_{0}$.

A subset $B$ of $X$ is said to be path connected if and only if for all $x$ and $y$ in $B$ there is a path from $x$ to $y$ in $B$.

Definition 2.1.2. Let $f_{1}$ and $f_{2}$ be two paths with the same initial $\left(a_{0}\right)$ and terminal $\left(b_{0}\right)$ points. A homotopy between two paths $f_{1}$ and $f_{2}$ is a continuous map $h:[0,1]^{2} \rightarrow X$ such that

$$
h(0, t)=f_{1}(t), h(1, t)=f_{2}(t) \forall t \in I \text { and } \quad h(s, 0)=a_{0}, h(s, 1)=b_{0} \forall s \in I .
$$

Two paths $f_{0}$ and $f_{1}$ are called homotopic, which we denoted by $f_{0} \sim f_{1}$, if there exists a homotopy between them. Homotopy is an equivalence relation on loops with the initial point $a_{0}$. By $[f]$ we denote the homotopy equivalence class of the loop $f$.

Definition 2.1.3. Let $f_{1}$ and $f_{2}$ be two paths on $X$ with $f_{1}(1)=f_{2}(0)$. Then the product of $f_{1}$ and $f_{2}$ is defined by

$$
\left(f_{1} \cdot f_{2}\right)(t)= \begin{cases}f_{1}(2 t) & \text { if } \quad 0 \leqslant t \leqslant \frac{1}{2} \\ f_{2}(2 t-1) & \text { if } \\ \frac{1}{2} \leqslant t \leqslant 1\end{cases}
$$

Definition 2.1.4. Let $X$ be a path connected topological space and $x \in X$. The fundamental group of the space $X$ at the base point $x$, is denoted by $\pi_{1}(X, x)$, and defined to be the set of all homotopy classes of loops $f$ with the initial point $x$ with respect to the product $\left[f_{1}\right]\left[f_{2}\right]=\left[f_{1} f_{2}\right]$.

Definition 2.1.5. Let $X$ be a Hausdorff space. Then $X$ is a topological manifold (manifold), if for each point of $X$ there is an open neighborhood of that is homeomorphic to $\mathbb{R}^{n}$ for some fixed number $n \geqslant 1$.

Clearly, a manifold is connected if and only if it is a path connected. Indeed, if any two different points can be joined by a path. Moreover, connected components of a manifold are closed and open therefore they themselves are manifolds.

Definition 2.1.6. A continuous function $f$ between two topological space $X$ and $Y$ is said to be a homeomorphism if and only if $f$ is bijection and $f^{-1}$ is continuous. Two topological spaces $X$ and $Y$ are homeomorphic, if there is a homeomorphism function between them.

Definition 2.1.7. A Local Homeomorphism is a continuous map $f: Y \longrightarrow X$ that has the following property: every point $y \in Y$ has an open neighborhood $V$ such that $f$ maps $V$ homeomorphically onto $f(V)$ where $f(V)$, is open in $X$.

If $X$ is a connected manifold, then the fundamental groups $\pi_{1}(X, x)$ and $\pi_{1}(X, y)$ are isomorphic, for all $x, y \in X$. We explain this statement in the following way. Since $X$ is connected, there is a path $\lambda$ from the initial point $x$ to the terminal point $y$ which joins these two points. Based on the fact $\lambda^{-1}$ is a inverse of the path $\lambda$ with $\lambda^{-1}(t)=\lambda(1-t) \forall t \in[0,1]$. Although $\lambda^{-1} \cdot \lambda \neq \lambda \cdot \lambda^{-1}$, both $\lambda^{-1} \cdot \lambda$ and $\lambda \cdot \lambda^{-1}$ are homotopic to a constant path. We take a loop class $[\gamma]$ with base point $x$, therefore $[\gamma]$ in $\pi_{1}(X, x)$. So we can follow it by a path $\lambda^{-1}$ from $y$ to $x$, following by a loop $\gamma$ to initial point $x$ and return to the terminal point $y$ by using the path $\lambda$. Then we have created a loop $\lambda^{-1} \gamma \lambda$ with the base point $y$, such that it is an element of the fundamental group $\pi_{1}(X, y)$. Then we get $\pi_{1}(X, x)=\lambda \pi_{1}(X, y) \lambda^{-1}$. Hence, there is an isomorphism from $\pi_{1}(X, x)$ to $\pi_{1}(X, y)$ as illustrated in the Figure 2.1.

Figure 2.1:

Definition 2.1.8. Let $X$ and $Y$ be two topological spaces. Then $Y$ is a covering space (or cover) of $X$ if there exists a surjective map $f: Y \rightarrow X$ such that for every $x \in X$ there exists a path connected open neighborhood $U$ of $x$, such that the inverse image of $U$ under $f$ is the union of disjoint open sets $D_{i}$ in $Y$, and each $D_{i}$ is mapped $f$ homeomorphically onto $U$. The open neighborhood $U$ is called an admissible neighborhood.

If $Y$ is a cover of $X$ under the surjective function $f$, then $f: Y \longrightarrow X$ is called the covering map and $(Y, f)$ is the covering space of $X$. If $X$ has a covering space $(Y, f)$, then $f$ is a local homeomorphism. The converse is not true in general, it is possible to construct a local homeomorphism which is onto but is not covering map as shown in the following example.

Example 2.1.9. Let $f:(0,10) \rightarrow \mathbb{S}^{1}$ be map defined by

$$
f(t)=(\cos t, \sin t) .
$$

Then $f$ is onto and a local homeomorphism map but $((0,10), f)$ is not a covering space of $\mathbb{S}^{1}$.
Definition 2.1.10. Suppose that $f: Y \rightarrow X$ is a covering map and $x \in X$. The fiber of $x$ is the set given by

$$
f^{-1}(x)=\{y \in Y \mid f(y)=x\} .
$$

Let $\rho^{\prime}: I \longrightarrow Y$ be a path in $Y$ and let $f: Y \longrightarrow X$ be a cover of $X$. Then $f \circ \rho^{\prime}: I \longrightarrow X$ is a path in $X$. Moreover, if $\rho_{1}^{\prime}$ and $\rho_{2}^{\prime}$ are two paths in $Y$ such that $\rho_{1}^{\prime} \sim \rho_{2}^{\prime}$, then $f \circ \rho_{1}^{\prime} \sim f \circ \rho_{2}^{\prime}$. The converse raises some natural questions. If we have a path $\rho: I \longrightarrow X$ in $X$, does there exist a path $\rho^{\prime}$ in $Y$ such that $f \circ \rho^{\prime}=\rho$, or if $\rho_{1}^{\prime}, \rho_{2}^{\prime}$ are two paths in $Y$ and $f \circ \rho_{1}^{\prime} \sim f \circ \rho_{2}^{\prime}$ is it true $\rho_{1}^{\prime} \sim \rho_{2}^{\prime}$ ? The answers of both these questions are positive as we will soon explains. Firstly, we will introduce new concepts in the following lemma.

Lemma 2.1.11. [35, p.181]
Given a compact metric space $X$, such that $X$ is the union of a collection of open sets $\left\{A_{i}, i \in I\right\}$, then for every $S \subset X$, there exists a $\zeta \in \mathbb{R}$ such that if the diameter of $S$ is less than $\zeta$ then $S$ contained in some open set $A_{i}$. The real number $\zeta$ is called a Lebesgues number of open cover.

Proof. Let $x \in X$, it is clearly seen that $x \in A_{i}$ for some $i \in I$. Choose a real number $\varepsilon_{x}>$ 0 , such that the open ball $B\left(x, 2 \varepsilon_{x}\right)$ of $x$ is contained in $A_{i}$ for some $i \in I$. Note that the space $X$ is the union of the collection of open balls $\bigcup_{x \in X} B\left(x_{i}, \varepsilon_{x}\right)$. Hence $X=\bigcup_{i=1}^{n} B\left(x_{i}, \varepsilon_{x_{i}}\right)$, for some finite set $\left\{x_{1}, x_{2}, \cdots, x_{n}\right\} \in X$, as $X$ is a compact metric space. Now suppose that $\zeta=\min \left\{\varepsilon_{x_{1}}, \varepsilon_{x_{2}}, \cdots, \varepsilon_{x_{n}}\right\}$ and the diameter of $S$ is less than $\zeta$. Then $S \subset A_{i}$ for some $i \in I$. Indeed, if $z \in S$, then $z \in B\left(x_{j}, \varepsilon_{x_{j}}\right)$ for $j \in\{1,2, \cdots, n\}$. Thus $S \subset B\left(x_{j}, 2 \varepsilon_{x_{j}}\right)$ then $S \subset A_{i}$, for some $i \in I$, as $B\left(x_{j}, 2 \varepsilon_{x_{j}}\right) \subset A_{i}$.

Definition 2.1.12. Let $X$ and $Y$ be two topological spaces, and $f: Y \rightarrow X$ be a covering map. Let $p$ be a path in $X$. A lift of $p$ is a path $p^{\prime}$ in $Y$ such that $f \circ p^{\prime}=p$.

Lemma 2.1.13. [36, p.64]
Given a covering map $f: Y \rightarrow \rightarrow X, y_{0} \in Y$ and $x_{0}=f\left(y_{0}\right)$. Then for any path $\rho$ in $X$ with initial point $x_{0}$ there is a unique path $\rho^{\prime}$ in $Y$ with initial point $y_{0}$ such that $f \circ \rho^{\prime}=\rho$.

Proof. Clearly, if $\rho$ is in the admissible neighborhood $U$, then there exists a unique path $\rho^{\prime}$ with the initial point $y_{0}$ such that $f \circ \rho^{\prime}=\rho$. Indeed, let $D$ be a path component of $f^{-1}(U)$ such that $y_{0} \in D$. Since each path component of $f^{-1}(U)$ is mapped topologically onto $U$ by $f$, then there exists a unique path $\rho^{\prime}$ in $Y$ with the initial point $y_{0}$ such that $f \circ \rho^{\prime}=\rho$.

In case $\rho$ is not contained in admissible neighborhood $U$. We can define $\rho$ as a product of shorter paths such that each of the shorter paths is contained in admissible neighborhood $U$. So, apply the previous argument on each of short paths then we can find a unique path $\rho^{\prime}$ in $Y$ with the required properties. The explanation of this argument is as follows. Assume that admissible neighborhoods $\left\{U_{i}\right\}$ covering $X$. The inverse image of admissible neighborhoods $\rho^{-1}(U)$ is open cover of the compact metric space $I$. Suppose that the number $r$ large as can as possible. Let $\frac{1}{r}<\zeta$ where $\zeta$ is Lebesgues number of covering. So, the interval $I=[0,1]$ can be divided into $r$ subinterval as follows $[0,1]=\left[0, \frac{1}{r}\right] \cup\left[\frac{1}{r}, \frac{2}{r}\right] \cup \cdots \bigcup\left[\frac{r-1}{r}, 1\right]$. It is clearly that $\rho$
maps each subinterval into admissible open neighborhoods in $X$. Thus, we have successfully defined a unique path $\rho^{\prime}$ over these subintervals .

Lemma 2.1.14. [36, p.68]
Given a covering map $f: Y \rightarrow X$. Then the sets $f^{-1}\left(a_{0}\right), \forall a_{0} \in X$, have the same cardinality.

Proof. Suppose that $a_{0}$ and $a_{1}$ are two different points in $X$. Let $\rho: I \rightarrow X$ be a path with initial point $a_{0}$ and terminal point $a_{1}$. We claim that there is a map $f^{-1}\left(a_{0}\right) \rightarrow f^{-1}\left(a_{1}\right)$ which is bijection. Assume that $b_{0} \in f^{-1}\left(a_{0}\right)$, and consider the lift $\rho$ is a path $\rho^{\prime}$ in $Y$ with initial point $b_{0}$ so that $f \circ \rho^{\prime}=\rho$. Now suppose that $b_{1}$ is a terminal point of the path $\rho^{\prime}$. Since the uniqueness of the lift starting at the point $b_{0}$ then by previous lemma $b_{1}$ ith the only possible terminal point. Thus $b_{0} \rightarrow b_{1}$ which is a required mapping. Similarly, by utilizing the inverse path $\bar{\rho}$, we can define a map $f^{-1}\left(a_{1}\right) \rightarrow f^{-1}\left(a_{0}\right)$. We notice that these maps are inverse each other, which implies that the map $f^{-1}\left(a_{0}\right) \rightarrow f^{-1}\left(a_{1}\right)$ is bijection. Thus for each $a_{0} \in X, f^{-1}\left(a_{0}\right)$ has the same cardinality.

We conclude from the above two lemmas, if we have a path connected space $X$ and a covering map $f$, then there exists a bijection between two different fibers. Thus all fibers have the same cardinality. This cardinality is said to be the degree of the covering map $f$, it may be finite or infinite.

Next we will explain how the group $\pi_{1}(X, x)$ acts on the fiber $f^{-1}(x)$, via homotopy lifting. Fix a point $x \in X$ and choose a point $y_{0} \in Y$ such that $y_{0} \in f^{-1}(x)$. Let $\gamma$ be a loop on $X$ based at the point $x$, then the lift of the loop $\gamma$ is a unique path $\bar{\gamma}$ in $Y$ with the initial point $y_{0}$ (Lemma 2.1.13). Note that the terminal point of this lifted path need not be $y_{0}$, however, it must be lie in the fiber over $x$. The terminal point $\bar{\gamma}[1]$, consequently, depends only on the class $\gamma$ in the fundamental group $\pi_{1}(X, x)$. This gives a right group action of the fundamental group $\pi_{1}(X, x)$ on the fiber $f^{-1}(x)$. This action is called the monodromy action of $\pi_{1}(X, x)$ on $f^{-1}(x)$ [30].

Definition 2.1.15. Given a covering map $f: Y \rightarrow X$ of degree $n$, and fundamental group $\pi_{1}(X, x)$ based at the point $x$. The monodromy action of $\pi_{1}(X, x)$ on each fiber gives a group homomorphism

$$
\rho: \pi_{1}(X, x) \longrightarrow S_{n},
$$

Figure 2.2:
this homomorphism is said to be monodromy representation of the covering map $f$, where $S_{n}$ is the symmetric group of $n$ points. The image of homomorphism $\rho$ is called monodromy group of covering map $f$ and denoted by $\operatorname{Mon}(Y, f)$.

Note that, the subgroup $\operatorname{Mon}(Y, f) \subset S_{n}$ is a transitive subgroup. Indeed, $Y$ is connected and for any two any indices $i$ and $j$ there is an element in the monodromy $\operatorname{group} \operatorname{Mon}(Y, f)$ such that taking $i$ to $j$.

Lemma 2.1.16. [30, p.87]
Suppose that $p: \pi_{1}(X, x) \rightarrow S_{n}$ is the monodromy representation for a path connected covering space $(Y, f)$ of $X$ of finite degree $n$. Then $\operatorname{Mon}(Y, f)$ is a transitive subgroup of $S_{n}$.

Proof. Take two points $x_{i}$ and $x_{j}$ in the fiber of $f$ over $x$. As $Y$ is path connected, we can find a path $\beta^{\prime}$ on $X$ with the initial point $x_{i}$ and the terminal point $x_{j}$. Let $\beta=f \circ \beta^{\prime}$ be the image of $\beta^{\prime}$ in $X$. Then $\beta$ is a loop in $X$ based at the point $x$, since both points $x_{i}$ and $x_{j}$ in $f^{-1}(x)$. Then we get that $p([\beta])$ is a permutation such that sends $x_{i}$ to $x_{j}$.

Moving from transitive subgroups of the fundamental group of the space to covers of the space is permitted by definition of monodromy representations. Suppose $\rho: \pi_{1}(X, x) \longrightarrow S_{n}$, is a homomorphism such that the image of the function $\rho$ is a transitive subgroup of the symmetric
group $S_{n}$. Let $K \subseteq \pi_{1}(X, x)$ be the subset in $\pi_{1}(X, x)$ of $X$ defined by

$$
K=\left\{[\beta] \in \pi_{1}(X, x) \mid \rho([\beta])(1)=1\right\}
$$

The subgroup $K$ has index $n$ in $\pi_{1}(X, x)$ such that it is correspondence with a connected covering space $\left(Y_{\rho}, f_{\rho}\right)$ of the space $X$. Note that the homomorphism $\rho$ is exactly a monodromy representation of the cover $Y$.

Lemma 2.1.17. Suppose that $f: Y \longrightarrow X$ is a covering map and $\rho_{1}^{\prime}, \rho_{2}^{\prime}$ are two paths in $Y$ such that they have the same initial point. If $f \circ \rho_{1}^{\prime} \sim f \circ \rho_{2}^{\prime}$, then $\rho_{1}^{\prime} \sim \rho_{2}^{\prime}$

Proof. Complete proof can be found in [27]
Definition 2.1.18. Two covering spaces $(Y, f)$ and $\left(Y^{\prime}, f^{\prime}\right)$ of the same space $X$ are isomorphic if there exists a homeomorphism mapping $\phi: Y \rightarrow Y^{\prime}$ such that $f^{\prime} \circ \phi=f$.

Definition 2.1.19. Let $f: Y \longrightarrow X$ be a covering. A homomorphism $\alpha: Y \longrightarrow Y$ is said to be deck transformation of the covering $f$ if $f \alpha=f$. The group formed by the set of all deck transformation is denoted by $\operatorname{Deck}(f)$.

Let $a$ be any point in the fiber $f^{-1}(x)$ for $x \in X$ then $\alpha(a)$ is still in fiber $f^{-1}(x)$ for any $\alpha \in \operatorname{Deck}(f)$. This implies that the group $\operatorname{Deck}(f)$ acts on the fiber $f^{-1}(b)$.

Now, assume that $b$ is initial point of $\gamma$ and $\widehat{\gamma}$ is a lift of $\gamma$ for $\gamma \in \pi_{1}(X, x)$. Then $\gamma b$ is the end point of the path $\gamma$. Furthermore, $\alpha(b)$ and $\gamma \alpha(b)$ are initial and end points of the path $\alpha \circ \widehat{\gamma}$ respectively. The fundamental group $\pi_{1}(X, x)$ also acts on the fiber $f^{-1}(b)$ via monodromy action such that the initial point of the lift $\gamma$ is $\alpha(b)$ and $\gamma \alpha(b)$ it's end point. By deck transformation we get $f \alpha \circ \hat{\gamma}=f \widehat{\gamma}=\gamma$, therefor $\alpha(\gamma(b))=\gamma \alpha(b)$. Thus the monodromy action of the fundamental group $\pi_{1}(X, x)$ commutes with the action of the group $\operatorname{Deck}(f)$, and we get the following result.

Proposition 2.1.20. Suppose that $f: Y \longrightarrow X$ is covering. Then the monodromy action on the fundamental group $\pi_{1}(X, x)$ commutes with the action of the group $\operatorname{Deck}(f)$ on the fiber $f^{-1}(x)$.

Proof. For proof see [36, p.68]
Lemma 2.1.21. Let $f: Y \longrightarrow X$ be a covering, $p \in X$ and $b \in f^{-1}(p)$. Then the group
$f\left(\pi_{1}(Y, b)\right)$ is a normal subgroup of the fundamental group $\pi_{1}(X, x)$ and the $\operatorname{Deck}(f)$ isomorphic to the monodromy group $G$.

Proof. For a proof see [28, p.134]
Definition 2.1.22. A covering map $f: Y \longrightarrow X$ is said to be Galois covering if $\operatorname{Deck}(f)$ acts transitively on some fibers $f^{-1}(b)$ and $Y$ is connected. If the degree of $f$ is finite then we say $f$ is finite.

The next result shows that if $f: Y \longrightarrow X$ is a Galois covering, then there is a homomorphism $\varphi_{b}$ from the fundamental group $\pi_{1}(X, x), x \in X$ to the group $\operatorname{Deck}(f)$ such that $\varphi_{b}$ is surjective and unique.

Proposition 2.1.23. Let $G$ be a deck transformation group $\operatorname{Deck}(f)$, where $f: Y \longrightarrow X$ is Galois covering such that for $b \in Y, x \in X, f(b)=x$. Let $[\gamma]$ be a loop class based on $x$. Then there is a unique surjective homomorphism $\varphi_{b}$ from the fundamental group $\pi_{1}(X, x)$ to the group $G$ with $\varphi_{b}[\gamma]=[\gamma] b$ (Recall that $[\gamma] b$ is end point of lift $\gamma$ with initial point $\left.b\right)$.

Proof. For a proof see [36, p.69]
Corollary 2.1.24. Let $[\gamma] \in \pi_{1}(X, x)$ and the end point of its lift is $b^{\prime} \in f^{-1}(x)$. Let $\varphi_{b}: \pi_{1}(X, x) \longrightarrow \operatorname{Deck}(f)$ with $\varphi_{b}[\gamma]=[\gamma] b$. Then $[\gamma] \cdot \operatorname{ker} \varphi_{b} \cdot[\gamma]^{-1}=\operatorname{ker} \varphi_{b^{\prime}}$

Proof. The lift of all elements of loop class $[\alpha] \in \operatorname{ker} \varphi_{b}$ is a loop based on $b$. So for $\left[\gamma \alpha \gamma^{-1}\right] \in$ $[\gamma] \cdot \operatorname{ker} \varphi_{b} \cdot[\gamma]^{-1}$, the lift for $\left[\gamma \alpha \gamma^{-1}\right]$ is a loop based on $b^{\prime}$. Thus $[\gamma] \cdot \operatorname{ker} \varphi_{b} \cdot[\gamma]^{-1} \subseteq \operatorname{ker} \varphi_{b^{\prime}}$. On the other hand if $\left[\alpha^{\prime}\right] \in \operatorname{ker} \varphi_{b^{\prime}}$ then the lift of $\alpha^{\prime}$ is a loop based at $b$. Similarly, $[\gamma]^{-1} \operatorname{ker} \varphi_{b^{\prime}}[\gamma] \subseteq$ $\operatorname{ker} \varphi_{b}$.

It is clear that form above, if the deck transformation group has trivial center, and if we pick any two points $b$ and $b^{\prime}$ in the fiber $f^{-1}(x)$ then $b=b^{\prime}$ if and only if the two homomorphism $\varphi_{b}$ and $\varphi_{b^{\prime}}$ are equal. So, the covering $f: Y \rightarrow X$ can be represented by the pair $\left(x, \varphi_{b}\right)$. This property allows us to construct the Hurwitz spaces.

### 2.2 Riemann Surfaces and Riemann Existence Theorem

Definition 2.2.1. Let $X$ be a topological space and $U \subset X$ be an open set in $X$. A homeomorphism $\theta: U \rightarrow V$ where $V \subset \mathbb{C}$ is said to be a complex chart or simple chart on $X$ and the open set $U$ is called the domain of the chart. If $\theta(p)=0$ for $p \in U$, then we say the chart centered at $p$.

Assume that $V$ and $W$ are two open sets of the complex plane and $\theta: U \rightarrow V$ is a complex chart. If $\psi: V \rightarrow W$ is holomorphic, one to one and onto, then the composition $\theta \circ \psi: U \rightarrow W$ is also a complex chart on $X[30]$.

Definition 2.2.2. For any two complex charts $\theta_{1}: U_{1} \rightarrow V_{1}, \theta_{2}: U_{2} \rightarrow V_{2}$ on $X$ we say $\theta_{1}$ and $\theta_{2}$ are compatible if either $U_{1} \cap U_{2}=\emptyset$ or $\theta_{2} \circ \theta_{1}^{-1}: \theta_{1}\left(U_{1} \cap U_{2}\right) \rightarrow \theta_{2}\left(U_{1} \cap U_{2}\right)$ is holomorphic. Note that $\theta_{1} \circ \theta_{2}^{-1}$ is holomorphic on $\theta_{2}\left(U_{1} \cap U_{2}\right)$ if $\theta_{2} \circ \theta_{1}^{-1}$ is holomorphic on $\theta_{1}\left(U_{1} \cap U_{2}\right)$. The bijective function $T=\theta_{2} \circ \theta_{1}^{-1}$ between the two charts is called the transition function.

Definition 2.2.3. Let $X$ be a topological space, $U \subset X$ be an open subset of $X$ and $V$ be an open subset of the complex plane. A complex atlas on $X$ is a collection $B=\left\{\theta_{j}: U_{j} \rightarrow V_{j}\right\}$ satisfying:
(1) $\bigcup_{j \in I} U_{j}=X$,
(2) any two charts $\theta_{j}$ and $\theta_{k}$ in $B$ are compatible.

Furthermore, if $Y \subset X$ and $B=\left\{\theta_{j}: U_{j} \rightarrow V_{j}\right\}$ is a complex atlas on $X$ then the collection $B_{Y}=\left\{\left.\theta_{j}\right|_{Y \cap U_{j}}: Y \cap U_{j} \rightarrow \theta_{j}\left(Y \cap U_{j}\right)\right\}$ is an atlas on $Y$ [30].

Let $A$ and $B$ be two complex atlases. If every chart in $A$ is compatible with every chart in $B$, then we say $A$ and $B$ are equivalent, that means two complex atlases $A$ and $B$ are equivalent if and only if $A \cup B$ is also a complex atlas. An equivalence class of complex atlases on $X$ is said to be complex structure.

Definition 2.2.4. A second countable Hausdorff connected topological space $X$ together with a complex structure is called a Riemann surface.

Note that a Riemann surface is a 1 -dimensional complex manifold. A compact Riemann surface
is homeomorphic to a sphere, or a connected sum of tori.
Definition 2.2.5. Suppose that $X$ is a Riemann surface and $f$ is holomorphic in a punctured neighborhood of $p \in X$. We say that $f$ has a pole if there exists a chart $\theta: U \rightarrow V$ with $p \in U$ such that $f \circ \theta^{-1}$ has a pole at $\theta(p)$. A function $f$ is said to be, meromorphic at a point $p$, if $f$ is holomorphic at $p$ or $p$ is a pole of $f$. If $f: X \rightarrow \mathbb{P}^{1}$ is a non-constant analytic function, then $f$ is called a meromorphic function. Moreover, a pair $(X, f)$ is called a cover where $f: X \rightarrow \mathbb{P}^{1}$ is a meromorphic function.

Proposition 2.2.6. Suppose that $f: X \rightarrow Y$ is a holomorphic map defined at $x \in X$, where $X$ and $Y$ are compact Riemann surfaces, . Then there exists a unique positive integer number $m$ such that for every chart $\theta^{\prime}: U^{\prime} \rightarrow V^{\prime}$ on $Y$ centered at $f(x)$, there exists a chart $\theta: U \rightarrow V$ on the complex structure on $X$ with $\theta(x)=0$ and $\theta^{\prime}\left(f\left(\theta^{-1}(z)\right)\right)=z^{m}$.

Proof. A complete proof can be found in [30, p.44]

The positive integer number $m$ is called the ramification index of $f$ at $x$ and denoted by $e_{x}$. A point $x \in X$ is called a ramified point of $f$, if $e_{x} \geqslant 2$. The image of a ramified point of $f$ is called a branch point.

Definition 2.2.7. A continuous function $f: X \longrightarrow Y$, where $X$ and $Y$ are compact Riemann surfaces, is called analytic, if for any two charts $\theta: V \longrightarrow W$ in $X$ and $\theta^{\prime}: V^{\prime} \longrightarrow W^{\prime}$ in Y with $f(V) \subset V^{\prime}$, the map $\theta^{\prime} \circ f \circ \theta^{-1}: \theta(V) \longrightarrow \theta\left(V^{\prime}\right)$ is holomophic.

Analytic functions between two Riemann surfaces $X$ and $Y$ in general is not coverings in the sense of the previous section. We can find a covering map $f$ between two Riemann surfaces $X$ and $Y$ without the ramified points. In the other words, if $f: X \rightarrow Y$ is a non-constant analytic function, then we can say that $f$ is a covering map onto its image without exceptional points $y \in Y$, where degree of $f$ is greater than the cardinality of $f^{-1}(y)$.

Proposition 2.2.8. Let $a_{1}, a_{2}, \cdots, a_{r}$ be $r$ points in Riemann sphere $\mathbb{P}^{1}$ and let $X=\mathbb{P}^{1}-\left\{a_{1}, \cdots, a_{r}\right\}$. If $\gamma_{1}, \gamma_{2}, \cdots, \gamma_{r}$ are loops around the points $a_{i}$, then the fundamental group $\pi_{1}(X, x)$ is generated by the homotopy classes $\left[\gamma_{i}\right]$ of loops $\gamma_{i}$. Moreover, $\left[\gamma_{1}\right]\left[\gamma_{2}\right] \cdots\left[\gamma_{r}\right]=1$.

Proof. See [30].

In the above proposition we have seen that in the Riemann surface $X$ if $f: Y \rightarrow X$ is branched at the elements $a_{i}$ then the homotopy classes of each loop $\gamma_{i}$ around $a_{i}$ is $\left[\gamma_{i}\right]$. Which implies that, the monodromy representation $\rho$ from the fundamental group $\pi_{1}(X, x)$ to the symmetric group $S_{n}$ is determined by $r$ permutation $\sigma_{1}, \cdots, \sigma_{r} \in S_{n}$. where $\rho\left(\gamma_{i}\right)=\sigma_{i}$ and $\sigma_{1} \cdots, \sigma_{r}=1$. If $\sigma=\left\{\sigma_{1}, \cdots, \sigma_{r}\right\}$, then the map $f: Y \longrightarrow \mathbb{P}^{1}$ is called of type $\sigma$.

In the previous section we understood that if $f: R \rightarrow \mathbb{P}^{1}$ is a meromorphic function from a Riemann surface to $\mathbb{P}^{1}$ in general f is not a covering if the set of branch points is non-empty. By restricting the domain to $R-f^{-1}(B)$ where $B=\left\{a_{1}, \ldots, a_{r}\right\}$ is the set of branch points, the meromorphic function $f$ is guaranteed to be a covering. Now we turn our attention to finite coverings of the punctured sphere, that is the Riemann sphere $\mathbb{P}^{1}$, which is removed a finite number points with monodromy group $G$. Further, we look at a relationship between the elements of the fundamental group of the puncture sphere $\mathbb{P}^{1} \backslash B$ and elements of the monodromy group G. According to this result we focus on the Riemann Existence Theorem . Now assume that $k(r):=\{z \in \mathbb{C}:|z|<r\}$ for $r>0$.

Lemma 2.2.9. Let $n$ be a natural number, Then the map $f_{n}$ from $k\left(r^{1 / n}\right)$ to $k(r)$ mapping $z$ to $z^{n}$ is a Galois covering and the monodromy group is cyclic of order $n$.

Proof. A complete proof can be found in [36, p.70].
Lemma 2.2.10. The Galois covering $f_{n}: k\left(r^{\frac{1}{n}}\right) \rightarrow k(r)$ and $f: A \rightarrow k(r)$ of degree $n$ and they are equivalent if $A$ is connected.

Proof. A complete proof can be found in [36, p.71].

Suppose that $\mathbb{P}^{1}=\mathbb{C} \cup\{\infty\}$ is the Riemann sphere and $B=\left\{b_{1}, \ldots, b_{r}\right\}$ is a set of branch points in $\mathbb{P}^{1}$. Let $D(p, r)=\{z \in \mathbb{C}:|z-p|<r\} ; r>0, p \in \mathbb{C}$ be a an open set centered at the point $p$. If $p=\infty$, then $D(p, r)=\left\{z \in \mathbb{C}:|z|>r^{-1}\right\} \cup\{\infty\}$. The Galois covering is obtained by removing the set of branch points in the Riemann sphere $\mathbb{P}^{1}$. In the other words, $\mathbb{P}^{1} \backslash B$ is a punctured sphere and $f: R \rightarrow \mathbb{P}^{1} \backslash B$ is a Galois covering and the group $G$ is its monodromy group. Note that, for any $b \in B$ there exists $r \in R$ such that $f(r)=b$ (because $f$ is onto). Moreover, for the two points $b$ and $r$ there exists open sets $U_{r}$ and $V_{p}$ respectively which are homeomorphic to the
disc $k(r)$. The above lemma guarantees that that the covering map $f: R \rightarrow \mathbb{P}^{1} \backslash B$ around each of the branch points $p$ maps $z$ to $z^{n}$.

Proposition 2.2.11. Let $D \backslash\{p\}$ be a punctured disc denoted by $D^{*}$ and $f: R \rightarrow \mathbb{P}^{1} \backslash B$ be a Galois covering. Then the components of $f^{-1}\left(D^{*}\right)$ are permuted transitively by the monodromy group $G$. Moreover, if $G_{F}$ is the stabilizer of $F$ in $G$, where $F$ is one component of $f^{-1}\left(D^{*}\right)$ then $G_{F}$ is cyclic.

Proof. A complete proof can be found in [36, p.72]

In the above proposition the generator of cyclic group is called canonical generator. For branch point $b$, the conjugacy class in $G$ which containing canonical generator is denoted by $C_{p}$.

Proposition 2.2.12. Let $\lambda$ be a loop based on the point $p^{*}, p^{*} \in D^{*}$ and let $\delta$ be another path joining two points $p^{*}$ and $q_{0}$ where $q_{0}=f(p) ; p \in R$. Then the map $\varphi_{p}$ from the fundamental group $\pi_{1}\left(\mathbb{P}^{1} \backslash B, q_{0}\right)$ to the group $G$ sends the homotopy class of $\gamma=\delta^{-1} \lambda \delta$ (representative element in $\left.\pi_{1}\left(\mathbb{P}^{1} \backslash B, q_{0}\right)\right)$ to the element in $C_{p}$.

Proof. For a proof see [36, p.73].

Let $b \in B$ be a branch point. In the fundamental group $\pi_{1}\left(\mathbb{P}^{1} \backslash B, q_{0}\right)$, there is a conjugacy class corresponding to the branch point $b$. We explain this statement in the following way. First we select an open disc $D(b, s)$ around the branch point $b$ for $s>0$ in which no point of $B \backslash\{b\}$ is contained in the disc $D(b, s)$. We draw a path $\delta$ from the base point $q_{0}$ of the fundamental group to some boundary point $v$ of the disc $D(b, s)$. Let $\lambda$ be a closed paths starting from the boundary point $v$ winding once counter clock wise around $D(b, s)$. The set of the close path $\delta^{-1} \lambda \delta$ is a conjugacy class with respect to the branch point $b$ where $\delta$ and $v$ vary and it is denoted by $\Sigma_{p}$.

Corollary 2.2.13. Let $\varphi_{b}: \pi_{1}\left(\mathbb{P}^{1} \backslash, q_{o}\right) \rightarrow G$ be surjective homomorphism. Then $\varphi_{b}\left(\Sigma_{p}\right)=C_{p}$.
Note that if $\varphi_{b}\left(\Sigma_{p}\right)=C_{p} \neq\{1\}$ then surjective homomorphism $\varphi_{b}$ is said to be admissible.
Corollary 2.2.14. Let $\mathbb{P}^{1}$ be the Riemann sphere. Let $B$ be a finite set in $\mathbb{P}^{1}$. Then there is one to correspondence between

- Isomorphism classes of meromorphic function $f: X \rightarrow \mathbb{P}^{1}$ branched at $B$
- transitive equivalence classes of permutation representations $\varphi_{b}: \pi_{1}\left(\mathbb{P}^{1} \backslash B\right) \rightarrow S_{n}$.

Definition 2.2.15. Let $f: X \rightarrow \mathbb{P}^{1} \backslash B$ be a finite Galois covering in which $B=\left\{a_{1}, a_{2}, \cdots, a_{r}\right\}$ is the set of branch points in $\mathbb{P}^{1}$. The ramification type $\bar{C}=\left\{C_{a_{1}}, C_{a_{2}}, \ldots, C_{a_{r}}\right\}$ of cover $f$ is defined to be the set set of non-trivial conjugacy classes in the group $G$.

Theorem 2.2.16. (Riemann Existence Theorem) Assume that $G$ is a finite group, $B \subset \mathbb{P}^{1}$ where $B=\left\{a_{1}, \ldots, a_{r}\right\}$. Let $\bar{C}=\left\{C_{a_{1}}, \ldots, C_{a_{r}}\right\}$ be a ramification type. Then there exists $G$ cover (branch-cover) of type $\bar{C}$ if and only if there exists generating tuple $\left(g_{1}, \cdots, g_{r}\right)$ of the group $G$ with $\prod_{i=1}^{r} g_{i}=1$ and $g_{i} \in C_{a_{i}}$ for $i=1,2, \ldots, r$.

The complete proof can found in [36]. This theorem tells us that if $G$ is a transitive subgroup of $S_{n}$ with elements $g_{1}, \ldots, g_{r}$, such that $G=\left\langle g_{1}, \ldots, g_{r}\right\rangle, \prod_{i=1}^{r} g_{i}=1$, and $g_{i} \neq 1$, for $i=1,2, \ldots, r$, then there exists a cover map $f: X \rightarrow \mathbb{P}^{1}$ branched at $B=\left\{a_{1}, \ldots, a_{r}\right\}$ such that $\operatorname{Mon}(Y, f)$ is equal to $G$.

Theorem 2.2.17. Let $X$ be a Riemann surface of genus $g$ and $f: X \rightarrow \mathbb{P}$ be a meromorphic function of degree $n$. Then

$$
\begin{equation*}
2(n+g-1)=\sum_{x \in X}\left(e_{x}-1\right) \tag{1}
\end{equation*}
$$

where $e_{x}$ is a ramification index of $f$ at $x$. Equation (1) is one form of the Riemann Hurwitz formula.

Proof. A complete proof can be found [30, p.52]
Definition 2.2.18. Suppose that $G$ acts on a finite set $\Omega$. The index of $x \in G$ on $\Omega$ is defined by

$$
\operatorname{ind}(x)=|\Omega|-\operatorname{orb}(x)
$$

where $\operatorname{orb}(x)$ is the number of orbits of $G$ on $\Omega$.
Theorem 2.2.19 (Riemann Hurwitz Theorem). Let $R$ be a Riemann surface of genus $g$ and $f: R \rightarrow \mathbb{P}^{1}$ be a meromorphic function of degree $n$. Let $G=\operatorname{Mon}(R, f)$ with $\delta_{1}, \cdots, \delta_{k} \in G^{k}$ with $\delta_{1} \ldots \delta_{k}=1$. Then

$$
\sum_{i=1}^{k} \operatorname{ind}\left(\delta_{i}\right)=2(n+g-1)
$$

Proof. A complete proof can be found [30, p.58]

Definition 2.2.20. Any tuples which satisfy the conditions laid out in Riemann Existence Theorem and Riemann Hurwitz formula are said to be admissible. Moreover, if $\sigma=\left\{\sigma_{1}, \sigma_{2}, \cdots, \sigma_{r}\right\}$ is an admissible tuple in the $G^{r}$, where $G$ is a transitive subgroup of the symmetric group $S_{n}$, then the pair $(G, \sigma)$ is said to be a genus $\mathbf{g}$ system of degree $n$.

### 2.3 Hurwitz space

In this section we aim to formally introduce the notation for Hurwitz spaces. Most of the results and definitions in this section are taken from [36]. For the remainder of this section, we assume that the center of the group $G$ is trivial. We denote the group of inner automorphisms of $G$ by $\operatorname{Inn}(G)$. The Riemann extension theorem and Corollary 2.1.24, play an important role in this section. Let $f: Y \rightarrow X$ be a Galois covering. Since $Z(G)=1$, it follows from Corollary 2.1.24 that if we pick any two points $b$ and $b^{\prime}$ in the fiber $f^{-1}(x)$ for $x \in X$, then $b=b^{\prime}$ if and only if $\varphi_{b}=\varphi_{b^{\prime}}$. We denote by $O_{r}$, the space of branch point sets in $\mathbb{C}$ of cardinality r. So $O_{r}=\left\{\mathbb{C}^{r} \backslash\left(a_{1}, \cdots, a_{r}\right) \in \mathbb{C}^{r} \mid\right.$ there exist i and j with $\left.a_{i}=a_{j}\right\}$. It is an open set of complex projective space of dimension r , and if we define the determinate to be $\prod_{i \neq j}\left(a_{i}-a_{j}\right)$, then it is the complement of the discriminate locus.

Let $A \leqslant \operatorname{Aut}(G)$ be arbitrary but fixed. Let $B \subseteq O_{r}$ and $\varphi: \pi\left(\mathbb{P}^{1} \backslash B, \infty\right) \rightarrow G$ be an admissible surjective homomorphism. Then two such pairs $(B, \varphi)$ and $\left(B^{\prime}, \varphi^{\prime}\right)$ are A-equivalent if $B=B^{\prime}$ and $\varphi^{\prime}=p \circ \varphi$ for some automorphism $p \in A$.

We define the Hurwitz space of $G$-covers to be the set of equivalence classes of the pairs $(B, \varphi)$ and we denoted it by $H_{r}^{A}(G)$.

We denoted by $[B, \varphi]$, the equivalence class of the pair $(B, \varphi)$. For each equivalence class $[B, \varphi]$ in the Hurwitz space $H_{r}^{A}(G)$, we identify a basis of neighborhoods as follows: Let $D_{1}, \ldots, D_{r}$ be $r$ pairwise disjoint discs centered around the $r$ branch points $b_{1}, \ldots, b_{r}$ in $B$. Let $B^{\prime}=\left\{b_{1}^{\prime}, \ldots, b_{r}^{\prime}\right\}$ be such that $b_{i}^{\prime} \in D_{i}$ and let $\left[B^{\prime}, \varphi^{\prime}\right]$ be the equivalence class of the pair $\left(B^{\prime}, \varphi^{\prime}\right)$. So the neighborhood of the equivalence classes $[B, \varphi]$ is the set of all equivalence class $\left[B^{\prime}, \varphi^{\prime}\right]$ where $\varphi^{\prime}$ is a composition of $\varphi$ and canonical isomorphism

$$
\pi_{1}\left(\mathbb{P}^{1} \backslash B^{\prime}, \infty\right) \rightarrow \pi_{1}\left(\mathbb{P}^{1} \backslash\left(D_{1} \cup \cdots \cup D_{r}\right), \infty\right) \rightarrow \pi_{1}\left(\mathbb{P}^{1} \backslash B, \infty\right) .
$$

This gives topology on $H_{r}^{A}(G)$. The Hurwitz space is denoted by $H_{r}^{i n}(G)$ if and only if $A=$ $\operatorname{Inn}(G)$.

Let the tuple $\overline{\mathrm{g}}=\left(g_{1}, \ldots, g_{r}\right) \in G^{r}$ be admissible and let $\rho \in A$ be any automorphism. Then the tuple $\rho(g)=\left(\rho\left(g_{1}\right), \ldots, \rho(\rho)\right)$ is also admissible and it corresponds to another cover $\varphi^{\prime}$ which is also admissible such that $\varphi^{\prime}=\rho \varphi$. Clearly, these two covers are A-equivalent. Hence the equivalence class of $G$-cover with the tuple $\rho(g)$ is represented by the equivalence class of the pair $(B, \varphi)$.

Proposition 2.3.1. Let $H_{r}^{A}(G)$ be the Hurwitz space and $B \subseteq O_{r}$, then the map $\psi_{A}: H_{r}^{A}(G) \rightarrow O_{r}$ sending the equivalence class of the pair $(B, \varphi)$ to the set of branch point $B$ is a covering.

Proof. For a proof see [36, 184].

Note that the monodromy homomorphism is completely determined by its action on the standard generators $\left\{\gamma_{1}, \ldots, \gamma_{r}\right\}$ of the group $\pi_{1}\left(\mathbb{P}^{1} \backslash B, \infty\right)$ because $\gamma_{1}, \ldots, \gamma_{r}$ generate $\pi_{1}\left(\mathbb{P}^{1} \backslash B, \infty\right)$ and the monodromy homomorphism $\varphi: \pi_{1}\left(\mathbb{P}^{1} \backslash B, \infty\right) \rightarrow G$ is an admissible surjection. The monodromy homomorphism $\varphi$ sends the generators of the group $\pi_{1}\left(\mathbb{P}^{1} \backslash B, \infty\right)$ to the group elements $g_{i}$ in $G$ such that $g_{1} \cdots g_{r}=1$ and $\left\langle g_{1}, \ldots g_{r}\right\rangle=G$. Let

$$
\mathscr{E}_{r}(G)=\left\{\left(g_{1}, \ldots g_{r}\right):\left\langle g_{1}, \ldots g_{r}\right\rangle=G \text { and } g_{1} \cdots g_{r}=1\right\}
$$

Then the group $A$ acts on the set $\mathscr{E}_{r}(G)$ by sending each $g_{i}$ to $\rho\left(g_{i}\right)$ for $\rho \in A$. The set of $A-$ orbits on $\mathscr{E}_{r}(G)$ is denoted by $\xi_{r}^{A}(G)$ in which $\zeta_{r}^{A}(G)=\mathscr{E}_{r}(G) / A$. Note that $\operatorname{Inn}(G) \simeq G / Z(G)$. If $A=\operatorname{Inn}(G)$, then $A \simeq G / Z(G)$ but $Z(G)=1$, therefore the set of $G$-orbits under conjugates is denoted $\xi_{r}^{\text {in }}(G)$.
Proposition 2.3.2. Let $\psi_{A}: H_{r}^{(A)}(G) \rightarrow O_{r}$ with $\psi_{A}([B, \varphi])=B$ be a covering and let $B_{0}$ be fix point in $O_{r}$, such that the fiber $\psi_{A}^{-1}\left(B_{0}\right)$ contains of all equivalence classes of the pairs $\left(B_{o}, \varphi\right)$. Then there is a bijection map between the fiber $\psi_{A}^{-1}\left(B_{0}\right)$ and the set $\mathscr{E}_{r}(G)^{A}(G)$ via sending conjugacy class of the pair $\left(B_{0}, \varphi\right)$ to $A$-equivalence class of $\left(g_{1}, \cdots, g_{r}\right)$, where $\left(\varphi\left[\gamma_{i}\right]\right)=g_{i}$
for $i=1 \cdots r$.

Proof. The complete proof can be found in [36, 194].

From the above proposition, we see that each tuple $\overline{\mathrm{g}}=\left(g_{1} \cdots g_{r}\right) \in \mathscr{E}_{r}(G)$ corresponds to a homomorphism $\varphi:(\pi \backslash B, \infty) \rightarrow G$. Furthermore, the Riemann existence theorem yields that any admissible tuple corresponds to a covering map $f: X \rightarrow \mathbb{P}^{1}$. Thus the space $H_{r}^{(A)}(G)$ is the set of equivalence classes of $G$-covers. A tuple $\overline{\mathrm{g}}=\left(g_{1} \cdots g_{r}\right)$ is of a ramification type $\overline{\mathrm{C}}=\left(C_{1}, \cdots, C_{r}\right)$ if $g_{i} \in C_{i}$ for all $i$, then $H_{r}^{(A)}(C) \subseteq H_{r}^{(A)}(G)$ and $H_{r}^{(A)}(\overline{\mathrm{C}})$ contains all equivalence class of pairs $[B, \varphi]_{A}$.

Definition 2.3.3. Let $\overline{\mathrm{C}}=\left(C_{1}, \cdots, C_{r}\right)$ be a ramification type. The Nielsen class is defined by

$$
N(\overline{\mathrm{C}})=\left\{\left(g_{1}, \ldots g_{r}\right) \mid g_{i} \in C_{i},\left\langle g_{1}, \ldots g_{r}\right\rangle=G \text { and } g_{1} \cdots g_{r}=1\right\}
$$

Definition 2.3.4. Let $r$ be integer number with $r \geqslant 2$. The braid group denoted by $B_{r}$ is generated by $r-1$ generators $\left\{Q_{1}, \cdots, Q_{r-1}\right\}$ satisfying the following relations

$$
\begin{equation*}
Q_{i} Q_{j}=Q_{j} Q_{i} \text { where }|i-j|>1 \tag{2}
\end{equation*}
$$

$$
\begin{equation*}
Q_{i} Q_{i+1} Q_{i}=Q_{i+1} Q_{i} Q_{i+1} \quad \text { for } i=1,2, \cdots, r-2 \tag{3}
\end{equation*}
$$

The term braid was defined by Emil Artin. Braids forms an infinite group. The relation 3 is said to be Yang Baxter equation. Furthermore, the two relations (3) and (2) together are called braid relations. Let $G$ be a finite group and $\overline{\mathrm{g}}=\left(g_{1} \cdots g_{r}\right) \in G^{r}$ a generating tuple of $G$. Then the braid group $B_{r}$ acts on $G^{r}$ via:

$$
\begin{equation*}
\left(g_{1}, \ldots g_{i}, g_{i+1}, \cdots\right)^{Q_{i}}=\left(g_{1}, \ldots g_{i+1}, g_{i+1}^{-1} g_{i} g_{i+1}, \cdots g_{r}\right) \quad \text { for } \quad i=1 \cdots r-1 \tag{4}
\end{equation*}
$$

This action is referred to as the braid action. The smallest set of tuples which contains $\overline{\mathrm{g}}=$ $\left(g_{1} \cdots g_{r}\right)$ is said to be the braid orbit of $g$ if it contains all image of $\bar{g}$ under $B_{r}$. Note that if $\overline{\mathrm{g}}=\left(g_{1} \cdots g_{r}\right) \in G^{r}$ is a Nielsen tuple then $\left\langle g_{1}, \ldots g_{r}\right\rangle=G$ and $\prod_{i=1}^{r} g_{i}=1$ which implies that

$$
\begin{aligned}
& g_{1} \cdots g_{i+1} \cdot g_{i+1}^{-1} \cdot g_{i} \cdot g_{i+1} \cdots g_{r}=1 \text { and } \\
& \left\langle g_{1}, \ldots, g_{i+1}, g_{i+1}^{-1} g_{i} g_{i+1}, \ldots g_{r}=1\right\rangle=G
\end{aligned}
$$

So the braid action can be restricted to an action on the set of Nielsen tuples. Assume that $C=\left(C_{1}, \cdots, C_{r}\right)$ is a ramification type of the tuple $\overline{\mathrm{g}}=\left(g_{1} \cdots g_{r}\right)$ where $C_{i}$ is a conjugacy class of $G$ containing $g_{i}$ for $i=1, \cdots, r$. Then the conjugacy classes $C_{i}$ are permuted by the braid action. So there is a unique homomorphism $\sigma: B_{r} \rightarrow S_{r}$ with $\sigma\left(Q_{i}\right)=(i, i+1)$. The kernel of this homomorphism is denoted by $B^{(r)}$ and is called the pure braid group. The pure braid elements generate a pure braid group by the following relation

$$
\begin{align*}
Q_{i j}= & Q_{j-1} \ldots Q_{i+1} Q_{i}^{2} Q_{i+1}^{-1} \ldots Q_{j-1}^{-1}  \tag{5}\\
& =Q_{1}^{-1} \ldots Q_{j-2} Q_{j}^{2} Q_{j-2} \ldots Q_{i} \tag{6}
\end{align*}
$$

for $1 \leqslant i \leqslant j \leqslant r$. Because of the braid group action, we can assume that the conjugacy classes in type $C$ are ordered in particular way. From nowon, we always assume that the same conjugacy classes in $C$ are adjacent and form a block in $C$. The braids $\left\{Q_{i j}\right\}_{i, j}$ are conjugate to each other in $B_{r}$ [22, p.19]. Note that the braid group $B_{r}$ acts on the fiber $\psi_{A}^{-1}\left(B_{0}\right)$ [proposition 2.3.2], that is, $B_{r}$ acts on the set $\zeta_{r}^{A}(G)$ via the braid group action, and this action commutes with the action of $\operatorname{Aut}(G)(\operatorname{Inn}(G))$ on tuples.

Definition 2.3.5. Let $X=\{1, \cdots, r\}$ be a non empty set. Then $P=\left\{p_{1}, \cdots, p_{s}\right\}$ with $p_{i} \subseteq X$ is called a partition of $X$ if $\bigcup_{i}^{r} p_{i}=X$ and $p_{i}$ and $p_{j}$ are disjoint set for $i \neq j$.

Definition 2.3.6. Let $X=\{1, \cdots, r\}$ be a non empty set and $P=\left\{p_{1}, \cdots, p_{s}\right\}$ be a partition of $X$ with stabilizer $S_{P}$ when $S_{P}$ is a subgroup of $S_{r}$, then the fiber of $S_{p}$ is called parabolic subgroup of $B_{r}$ and it is denoted by $B_{p}$.

Let $\overline{\mathrm{C}}=\left(C_{1}, \cdots, C_{r}\right)$ is a ramification type. For the rest of this thesis we order elements in the type $\overline{\mathrm{C}}$ in the following way $C_{i}=C_{j}$ for $1 \leqslant i \leqslant j \leqslant r$ if and only if $i=j$. Let $P$ be a partition of the set $C$, then the parabolic subgroup $B_{P}$ of $B_{r}$ preserves the order of conjugacy class so $B_{p}$-orbit may be shorter than the $B_{r}$-orbits as much as by the factors of $\left[S_{r}: S_{P}\right]$ which switching
to the $B_{P}$-orbits may be useful for our computations.
Proposition 2.3.7. Let $\overline{\mathrm{C}}=\left(C_{1}, \cdots, C_{r}\right)$ is a ramification type and $N(C)$ be a Nielsen class. Then there is a one to one correspondence between $B_{b}$-orbit on $N(\overline{\mathrm{C}})$ and connected components of $H_{r}^{\text {in }}(G)$.

Proof. A complete proof can be found [37]

The above proposition guarantees us that there is a one to one correspondence between $B_{p^{-}}$ orbits on the Nielsen class and connected components of $H_{r}^{i n}(\overline{\mathrm{C}})$. In our thesis we focus on the Hurwitz space, more precisely $H_{r}^{i n}(\overline{\mathrm{C}})$ of $H_{r}^{\text {in }}(G)$. The MapClass package was designed by James ,Magaard, Shpectorov and Völkein to find braid orbits for a given group and given tuple.

### 2.4 Primitive Permutation groups

Definition 2.4.1. Let $G$ be a group and $\Omega$ be a non empty set. Then a right group action of $G$ on $\Omega$ is a function $*: X \times G \longrightarrow \Omega$ satisfying the following conditions
(1) $x * e=x$ for $x \in \Omega$, where $e \in G$ is the identity;
(2) $x *(g h)=(x * g) * h$ for $g, h \in G$ and $x \in \Omega$.

The action of $G$ on $\Omega$ is called transitive, if for every $x, y \in X$ there exists $g \in G$ such that $x g=y$. The group $G$ acts faithfully on $X$ if for any $g, h \in G$ where $g \neq h$ there exists $x \in X$ such that $x g \neq x h$. Equivalently, if $g \neq e$, then $x g \neq x$ for some $x$.

Definition 2.4.2. Let $G$ be a group acting on $\Omega$. A block of imprimitivity for $G$ is a non-empty set $\Delta \subset \Omega$ such that for all $g \in G$ either $\Delta g=\Delta$ or $\Delta g \bigcap \Delta=\emptyset$. If $|\Delta|=1$, then $\Delta$ is called a trivial block.

Lemma 2.4.3. If $G$ is transitive on $\Omega$ and $\Delta$ is a block of imprimitivity then $\{\Delta g \mid g \in G\}$ is a partition of $\Omega$.

Proof. [5, 142]
Example 2.4.4. If $H<K<G$ are subgroups of $G$, then $G$ acts transitively on $G / H$ and set $\Delta=\cup H k, k \in K$ is a block of imprimitivity.

Definition 2.4.5. A group $G$ acting on $\Omega$ is called primitive if $G$ acts on $\Omega$ transitively and there is no partition of $\Omega$ preserved by $G$. In other words, $G$ is said to act primitively on $\Omega$ if $\Omega$ contains no nontrivial blocks. If a primitive group $G$ acts faithfully on $\Omega$, then $G$ is called primitive permutation group.

Definition 2.4.6. Let $G$ be a group which acts on the non empty set $\Omega$. Then the stabilizer subgroup of $\omega \in \Omega$ is defined by

$$
G_{\omega}=\{g \in G \mid \omega g=\omega\} .
$$

Theorem 2.4.7. Let $G$ acts transitively $\Omega$. Then $G$ is primitive if and only if $G_{\omega}$ is a maximal subgroup of $G$.

Proof. Suppose that $G$ is primitive. Let $G_{\omega} \leqslant H \leqslant G$ for a subgroup $H$ in $G$. Define $\Delta=$ $\{\omega h \mid h \in H\}$. Let $g \in G$ and $\alpha \in \Delta g \bigcap \Delta$. Then $\alpha \in \Delta g$ and $\alpha \in \Delta$ which implies that $\alpha=$ $\omega h_{1} g=\omega h_{2}$ where $h_{1}, h_{2} \in H$. Therefore, $\omega h_{1} g h_{2}^{-1}=\omega$. Thus, $h_{1} g h_{2}^{-1} \in G_{\omega} \leqslant H$. Hence $g=h_{1}^{-1}\left(h_{1} g h_{2}^{-1}\right) h_{2} \in H$ and so $\Delta g=\Delta$. Hence $\Delta$ is block. Since $G$ is primitive, we have $\Delta=\{\omega\}$ or $\Delta=\Omega$. If $\Delta=\{\omega\}$, then $\omega h=\omega$ for each $h \in H$, which implies that $h \in G_{\omega}$ and hence $G_{\omega}=H$. If $\Delta=\Omega$, then $\omega g \in \Omega=\Delta$ for all $g \in G$. Therefore, $\omega g=\omega h$ for some $h \in H$ which implies that $\omega g h^{-1}=\omega$. So $g h^{-1} \in G_{\omega} \leqslant H$. Thus $g \in H$. Implying, $G=H$. Hence $G_{\omega}$ is a maximal subgroup of $G$.

Conversely, suppose that $G$ is not primitive. Then there exists a non trivial block $\Delta$ for $G$. Let $\omega \in \Delta$. Then $G_{\omega} \leqslant G_{\Delta}$. Indeed for $g \in G_{\omega}, \omega g=\omega$, and so we have $\Delta g \bigcap \Delta \neq \phi$ which implies that $\Delta g=\Delta$. So if $g \in G_{\Delta}$ then indeed $G_{\omega} \leqslant G_{\Delta}$. Now suppose that $G_{\omega}=G_{\Delta}$ and $\alpha \in \Delta$. Since $G$ acts transitively on $\Omega$, then there exists $g \in G$ such that $\alpha=\omega g$. Thus $\Delta g \cap \Delta \neq \phi$, and it follows that $g \in G_{\Delta}=G_{\omega}$ and so $\omega g=\omega$. Then $\alpha=\omega$ and $\Delta=\{\omega\}$ : a contradiction. Suppose that $G_{\Delta}=G$ and $\alpha \in \Omega$. Since there exists $g \in G$ such that $\alpha=\omega g$, we have $\alpha \in \Delta g=\Delta$; so $\Delta=\Omega$, a contradiction. Thus $G_{\omega}<G_{\Delta}<G$. Hence $G_{\omega}$ is not maximal.

Let $G$ be a group which acts on the non empty set $\Omega$, then define $G_{\omega}^{g}$ by $G_{\omega}^{g}=\left\{g^{-1} h g \mid h \in G_{\omega}\right\}$. Note that if $\alpha=\omega g$ then $G_{\alpha}=G_{\omega}^{g}$. If $G$ is a transitive permutation group acting on a non empty set $\Omega$, and $\alpha \in \Omega$, then for some $g \in G, \alpha=\omega g$ so $G_{\alpha}=G_{\omega g}=G_{\omega}^{g}$. Which means that
if $G_{\omega}$ and $G_{\alpha}$ are any two stabilizer subgroups of a transitive permutation group $G$, then they are conjugate in $G$. $G_{\omega}$ is maximal subgroup in $G$ then $G_{\omega g}$ is a maximal subgroup $\forall g \in G$.

Definition 2.4.8. Assume that $G$ is a group. A non-trivial normal subgroup $N$ of $G$ is called minimal normal subgroup if for any non-trivial normal subgroup $M$ in $G$ such that $M \leqslant N$ then $M=N$.

Clearly, the intersection of any two different minimal normal subgroup of the group $G$ is trivial. Indeed, if $N_{1}$ and $N_{2}$ are two minimal normal subgroups of $G$, then $N_{1} \cap N_{2} \unlhd G, N_{1} \cap N_{2} \leqslant N_{1}$ and $N_{1} \cap N_{2} \leqslant N_{2}$. Thus, $N_{1} \cap N_{2}=\{1\}$ (by minimality of $N_{1}$ and $N_{2}$ ). It follows that, $N_{1} \leqslant$ $C_{G}\left(N_{2}\right)$ and $N_{2} \leqslant C_{G}\left(N_{1}\right)$ as $\left[N_{1}, N_{2}\right] \leqslant N_{1} \cap N_{2}=\{1\}$.

Definition 2.4.9. Let $G$ be a simple group . Then $L$ is called almost simple group if

$$
G \leqslant L \leqslant \operatorname{Aut}(G) .
$$

Let $G$ be a non abelian simple group. Then a finite group is almost simple if and only if it is isomorphic to a group $L$ such that $\operatorname{Inn}(G) \leqslant L \leqslant \operatorname{Aut}(G)$.

Let $M$ be a maximal subgroup of an almost simple group $L$. Then the permutation action of the group $L$ on the the right cosets of $M$ via right multiplication is primitive. Thus $L$ is a primitive subgroup of symmetric group $S_{n}$ where $[L: M]=n$. To describe the maximal subgroups of $S_{n}$, we require knowledge about the maximal subgroups of all almost simple groups. If there exists a normal subgroup $G$ in $L$ such that $G$ is simple, then $C_{L}(G)=1$.

### 2.5 General criteria for determining possible signatures of ramification types

Assume that $f: X \longrightarrow \mathbb{P}^{1}$ is a meromorphic function of degree $n$, where $X$ is a compact Riemann surface of genus $g$. We have shown that if $\left\{a_{1}, a_{2}, \cdots, a_{r}\right\}$ is a set of branch points in $\mathbb{P}^{1}$, then the fundamental group $\pi_{1}\left(\mathbb{P}^{1}-\left\{a_{1}, a_{2}, \cdots, a_{r}\right\}, x_{0}\right)$, where $x_{0} \in \mathbb{P}^{1}-\left\{a_{1}, a_{2}, \cdots, a_{r}\right\}$, acts transitively on the fiber $f^{-1}\left(x_{0}\right)$. Now, if $G=\operatorname{Mon}(X, f)$, we are interested in the structure of the group $G$ when the compact Riemann surface $X$ is of genus $g \leqslant 2$ and the meromorphic
function $f$ can not be written as a composition of two homomorphic functions $f_{1}$ and $f_{2}$ where $f_{1}$ and $f_{2}$ are two functions of degree greater than or equal to two.

Definition 2.5.1. Let $f$ be a function. Then $f$ is called indecomposable, if $f$ can not be written as a composition of two functions of degree greater than one. In the other words, $f$ is decomposable if and only if $f=f_{1} \circ f_{2}$ where the degree of $f_{1}$ and $f_{2}$ are both greater than one. Theorem 2.5.2. Given a covering map $f: Y \longrightarrow X$ of a finite degree $n$. Then $f$ is indecomposable if and only if the corresponding monodromy action is primitive.

Proof. A complete proof can be found in [36, p.47].
Definition 2.5.3. Suppose that $\left\{x_{1}, x_{2}, \cdots, x_{r}\right\}$ is a generating set such that

$$
x_{1} \cdot x_{2} \cdots \cdot x_{r}=1
$$

If we set $d_{i}=\left|x_{i}\right|$, then we call $\left(d_{1}, d_{2}, \cdots, d_{r}\right)$ the signature of the tuple $\left(x_{1}, x_{2}, \cdots, x_{r}\right)$. To standardize matters we generally assume $x_{i}$ such that $d_{1} \leqslant \cdots \leqslant d_{r}$.

Definition 2.5.4. Assume that $G$ is a transitive group of $S_{n}$. A genus $g$ - system is a tuple $\bar{x}=\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ such that for all $1 \neq x_{i} \in G 1 \leqslant i \leqslant r, x_{1}, \cdots x_{r}=1$ and $G=\left\langle x_{i} \mid 1 \leqslant i \leqslant r\right\rangle$

$$
\begin{equation*}
\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right) \neq 2(n+g-1) . \tag{7}
\end{equation*}
$$

Note that a tuple $\overline{\mathrm{x}}$ is said to be non-genus g -system if $1 \leqslant i \leqslant r, x_{1}, \cdots x_{r} \neq 1, G \neq\left\langle x_{i} \mid 1 \leqslant i \leqslant r\right\rangle$ or $\sum_{i=1}^{r} i n d\left(x_{i}\right)=2(n+g-1)$. Furthermore we say a group $G$ is not of type $\overline{\mathrm{x}}$ if and only if $\overline{\mathrm{x}}$ is a non-genus g -system.

Theorem 2.5.5 (Ree ). Assume that $G$ acts transitively on a set of size $n$. If $x_{1}, x_{2}, \cdots, x_{r}$ are permutations generating $G$ with $x_{1} \cdot x_{2} \cdots x_{r}=1$, then $O_{1}+O_{2}+\cdots+O_{r} \leqslant(r-2) n+2$ where $O_{i}$ is the number of orbits of $\left\langle x_{i}\right\rangle$.

Ree's Theorem is a consequence of the Riemann Hurwitz formula but can be proved independent by see for example [6]. The Ree Theorem means that if $x_{1}, x_{2}, \cdots, x_{r}$ are permutations generating a transitive group on a set of size $n$, then sum of the numbers of cycles of the $x_{i}$ is less than or equal to $(r-2) n+2$. We will illustrate this with the following example.

Example 2.5.6. In the Mathieu group $M_{12}$ if $\left(x_{1}, x_{2}, \cdots, x_{r}\right) \in M_{12}^{r}$, in its action on the right cosets of maximal subgroup $M_{11}$. $M_{12}$ is not of types $(2 B, 3 A, d)$, and $(2 B, 4 B, d)$ where $d$ representative conjugacy classes of any order. As $\left(O_{2 B}=8\right)+\left(O_{3 A}=6\right)+O_{d}>(r-2) n+2=$ 14. So Ree's transitivity condition fails. Hence $M_{12}$ is not of type ( $2 B, 3 A, d$ ). Similarly, $M_{12}$ can not be of type $(2 B, 4 B, d)$.

Definition 2.5.7. Let $\bar{x}=\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ be a tuple of elements of order $d_{1}, d_{2}, \cdots, d_{r}$ respectively. The Zariski number denoted by $A(\bar{x})$ and defined by

$$
A(\bar{x})=\sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}} .
$$

## Proposition 2.5.8. (Zariski Condition)[26]

Let $G$ be a finite group acts transitively and faithfully on $\Omega$. Suppose that $\bar{x}=\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ is an admissible tuple, where $r \geqslant 3$. Then $A(\bar{x}) \geqslant \frac{85}{42}$.

Proof. A complete proof can be found in [26]
Definition 2.5.9. Assume that $G$ is a finite group. The symmetric genus of $G$ is denoted to be $g(G)$ and defined by the smallest integer $g$ such that $G$ acts faithfully as automorphisms of the surface and orientably on a closed orientable surface $S_{g(G)}$ of genus $g(G)$.

The symmetric genus of $G$ is given by $g(G)=\frac{|G|}{2}(N-2)+1$, where

$$
N=\min _{\bar{x}}\left\{A(\bar{d}) \mid \bar{d}=\operatorname{signature}(\bar{x}), G=\langle\bar{x}\rangle, \prod_{\bar{x}} x_{i}=1\right\} .
$$

## Theorem 2.5.10. (Marston Conder)

A. The symmetric genus of Mathieu group $M_{11}$ is 631 with a minimal genus action arising from $(2,4,11)$ generation of $M_{11}$.
B. The symmetric genus of Mathieu group $M_{12}$ is 3169 with a minimal genus action arising from $(2,3,10)$ generation of $M_{12}$.
C. The symmetric genus of Mathieu group $M_{22}$ is 34849 with a minimal genus action arising from $(2,5,7)$ generation of $M_{22}$.
D. The symmetric genus of Mathieu group $M_{23}$ is 1053361 with a minimal genus action arising from $(2,4,23)$ generation of $M_{23}$.
E. The symmetric genus of Mathieu group $M_{24}$ is 10200961 with a minimal genus action arising from $(3,3,4)$ generation of $M_{24}$.

Complete proofs can be found in [6]. In the light of this theorem, we can eliminate some signatures of possible generating sets of the group $G$. On the other hand, the above theorem is not enough to find the final list of possible signatures. There exist some other techniques that we will explain later.

Theorem 2.5.11. Let $X$ be a Riemann surface of genus zero, and $G$ be a sporadic simple group. Then there is a non-constant meromorphic function $f$ such that $G$ is a composition factor of monodromy group $\operatorname{Mon}(X, f)$ if and only if $F^{*}(G)$ is isomorphic of one of the elements of $\left\{M_{11}, M_{12}, M_{22}, M_{23}, M_{24}, J_{1}, J_{2}, H S, C o_{3}\right\}$.

The complete proof can be found [24]. The ideas contained in these theorems require knowledge about fixed point ratios of primitive permutation representations of the almost simple groups. In the next definition we will define fixed point ratio and upper bound of fixed point ratio.

Definition 2.5.12. Suppose that $G$ acts on the set $\Omega$. Then the fixed point ratio of $x \in G$ on a set $\Omega$ is defined by $\left\{\frac{f(x)}{n}\right\}$ where $f(x)$ is the number of fixed points of $x$ on $\Omega$ and $n=|\Omega|$.

In our work we are interested in almost simple groups $L$ with $F^{*}(L)=G$, and $x \in L$ acts by right translation on the right cosets of some maximal subgroups $M$ of $L$. The number $\mathrm{b}(G)$ is defined by

$$
\mathrm{b}(G):=\operatorname{Max}\left\{\left.\frac{f(x)}{n} \right\rvert\, n=[L: M] ; M \nsupseteq G, x \in M\right\} .
$$

is the least upper bound for all fixed point ratios of $x$ occurring in any transitive G-action.
Example 2.5.13. The Mathieu group $M_{11}$ has the following conjugacy classes of maximal subgroups: $M_{10}, L_{2}(11), M_{9} .2, S_{5}$ and $M_{8}[7]$. Recall, the set $\overline{\mathrm{C}}=C_{g_{1}} \ldots, C_{g_{r}}$ of conjugacy classes of a group $G$ such that $g_{i} \in C_{g_{i}}$ is called ramification type of the cover $f: X \rightarrow P$. The Mathieu group $M_{11}$ has 10 conjugacy classes which are $C=\{1 A, 2 A, 3 A, 4 A, 5 A, 6 A, 8 A, 8 B, 11 A, 11 B\}$. If $M=M_{10}$ then $\left[M_{11}: M\right]=11$ and the number of fixed point of $g_{i} \in C=\{2 A, 3 A, 4 A, 5 A, 6 A, 8 A, 8 B, 11 A, 11 B\}$ in $M_{11}$ acting by translation on right coset of $M_{10}$, is $\{3,2,3,1,0,1,1,0,0\}$. Therefore the max-
imum fixed point ratio of in this action is equal to $\frac{3}{11}$. Similarly, the maximal fixed point ratios on other maximal subgroups $L_{2}(11), M_{9} .2, S_{5}, M_{8}$ are $\frac{4}{12}, \frac{7}{55}, \frac{10}{66}$ and $\frac{13}{165}$ respectively. Hence the maximal fixed ratio is $\frac{4}{12}=\frac{1}{3}=b\left(M_{11}\right)$.

Definition 2.5.14. A group $G$ is called a genus $\mathbf{g}$ - group if and only if there exists a compact Riemann surface $X$ of genus $g$ and meromorphic function $f: X \rightarrow \mathbb{P}^{1}$ such that $G=\operatorname{Mon}(X, f)$. If a group $G$ is a composition factor of, $\operatorname{Mon}(M, f)$, then $G$ is said to be genus $\mathbf{g}$ composition

## factor.

Lemma 2.5.15. Suppose that $G$ is a permutation group acting on $n$-element the set $\Omega$. Let $x_{i} \in G$ then the following holds.

1. $\operatorname{ind}\left(x_{i}\right)=n-\sum_{j=1}^{d_{i}} \frac{1}{d_{i}} f\left(x_{i}^{j}\right)$ where $d_{i}=\left|x_{i}\right|$ and $f\left(x_{i}\right)$ is the number of fixed points of $x_{i}$ on $\Omega$;
2. If $G=<x_{1}, x_{2}, \cdots, x_{n}>$ and $x_{1} \cdot x_{2} \cdots, x_{n}=1$, then one the following are true.
a. $A(\overline{\mathrm{x}}) \geqslant \frac{85}{42}$.
b. $G$ is solvable group and $G$ is of type $(2,3,6),(2,2, d),(2,4,4),(3,3,3)$ or $(2,2,2,2)$.
c. $G$ of type $(2,3,3)$ and $G \simeq A_{4}$.
d. $G$ of type $(2,3,4)$ and $G \simeq S_{4}$.
e. $G$ of type $(2,3,5)$ and $G \simeq A_{5}$.

Proof. Complete proof can be found in [12].
Definition 2.5.16. Let $G$ be a group and let
$\overline{\mathrm{x}}=\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ such that $G=<x_{1}, x_{2}, \cdots, x_{r}>$ and $x_{1} \cdot x_{2} \cdots x_{r}=1$
$\overline{\mathrm{y}}=\left(y_{1}, y_{2}, \cdots, y_{s}\right)$ such that $G=<y_{1}, y_{2}, \cdots, y_{s}>$ and $y_{1} \cdot y_{2} \cdots, y_{s}=1$
Then we say $\overline{\mathrm{y}}<\overline{\mathrm{x}}$ if and only if $A(\overline{\mathrm{y}})<A(\overline{\mathrm{x}})$ and $\overline{\mathrm{y}}$ is minimal in $G$ if $\overline{\mathrm{y}}$ is a minimal with respect to $<$.

Recall the Riemann Hurwitz formula $\sum_{i=1}^{k} \operatorname{ind}\left(x_{i}\right)=2(n+g-1)$ where a group $G$ has a subgroup $M$ such that $[G: M]=n$ and $\overline{\mathrm{x}}=\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ is a genus $g$-system when $x_{i} \in G$ acts on the right cosets of $M$ by right multiplication . The left side of Riemann Hurwitz formula can be
written as $n A(\bar{x})-n B(\bar{x})$ where $B(\bar{x})=\left(\frac{1}{n}\right) \sum_{i=1}^{r} \sum_{j}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}, f\left(x_{i}\right)$ are the number of fixed points of $x_{i}$ and $\left|x_{i}\right|=d_{i}$. Moreover $n B(\overline{\mathrm{x}})$ can be bounded above by $A(\overline{\mathrm{x}}) b(G)$, hence $n A(\overline{\mathrm{x}})-n B(\overline{\mathrm{x}})>$ $n A(\overline{\mathrm{x}})(1-b(G))$.

The following lemma is useful, it is proved in [24].
Lemma 2.5.17. Let $G$ be a finite group and $\bar{x}$ be minimal in $G$. If $\frac{f(g)}{[G: M]}<\frac{A(\bar{x})-2}{A(\bar{x})}$ for all $(g, M)$, then $G$ is not a genus zero group.
Lemma 2.5.18. Let $G$ be a finite group and $\overline{\mathrm{x}}$ be minimal in $G$. If $\frac{f(g)}{[G: M]}<\frac{A(\bar{x})-2}{A(\bar{x})}$ for all $(g, M)$, then $G$ is not a genus one group.

Proof. Suppose that $\bar{y}$ is a generating genus one system. If $G$ is a genus one group, then the Riemann Hurwitz formula implies that $\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)=2(n+1-1)=2 n$. In the other hand, the left side of the Riemann Hurwitz formula can be written in the form

$$
\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)=n A(\bar{y})-n B(\bar{y})>n A(\bar{y})-n A(\bar{y}) b(G)
$$

Since $b(G)=\operatorname{Max}\left(\frac{f(g)}{[G: M]}\right)$, then $n A(\bar{y})-n B(\bar{y})>n A(\bar{y})-n A(\bar{x}) \frac{A(\bar{y})-2}{A(\bar{x})}$ therefore we get $\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)>2 n \frac{A(\bar{y})}{A(\bar{x})}$ but $\bar{x}$ is minimal then $\frac{A(\bar{y})}{A(\bar{x})} \geqslant 1$.
Hence $\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)>2 n$. Which is impossible because by hypothesis $\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)=2 n$.
Thus $G$ is not a genus one group.
In the next lemma we will show that the group $G$ does not possess a genus two system if $\frac{f(g)}{[G: M]}<$ $\frac{A(\bar{x})-2}{A(\bar{x})}-\frac{1}{[G: M]}$
Lemma 2.5.19. Let $G$ be a finite group and assume that $\overline{\mathrm{x}}$ be minimal in $G$. If $\frac{f(g)}{[G: M]}<\frac{A(\bar{x})-2}{A(\bar{x})}-$ $\frac{1}{[G: M]}$ for all $(g, M)$, then $G$ is not a genus two group.

Proof. If $G$ were a genus two group with genus 2-system $\bar{y}$, then the Riemann Hurwitz formula would imply that $\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)=2(n+2-1)=2 n+2$. The left hand side of the Riemann Hurwitz formula can be written in the form

$$
\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)=n A(\bar{y})-n B(\bar{y})>n A(\bar{x})-n A(\bar{x}) b(G)
$$

where $b(G)=\operatorname{Max}\left(\frac{f(g)}{[G: M]}\right)$. By hypothesis $b(G)<\frac{A(\bar{x})-2}{A(\bar{x})}-\frac{1}{[G: M]}$. We have

$$
\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)>n A(\bar{y})-n A(\bar{y})\left(\frac{A(\bar{x})-2}{A(\bar{x})}-\frac{1}{[G: M]}\right)=2 n \frac{A(\bar{y})}{A(\bar{x})}+A(\bar{y})
$$

Thus $\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)>2 n \frac{A(\bar{y})}{A(\bar{x})}+A(\bar{y})$. Since $\frac{A(\bar{y})}{A(\bar{x})} \geqslant 1$ by minimality of $\overline{\mathrm{x}}$.
So, $2 n+2=\sum_{i=1}^{k} \operatorname{ind}\left(y_{i}\right)>2 n+A(\overline{\mathrm{y}})>2 n+2$ if and only if $A(\overline{\mathrm{y}}) \geqslant \frac{85}{42}$. which is contradiction.
Hence $G$ is not a genus two group

Note that if any system $\overline{\mathrm{x}}$ satisfying the condition of Lemma 2.5.19 above, then it is not a genus zero or one system i.e If $\frac{f(g)}{[G: M]}<\frac{A(\bar{x})-2}{A(\bar{x})}-\frac{1}{[G: M]}<\frac{A(\bar{x})-2}{A(\bar{x})}$, then by Lemma 2.5.17 and Lemma2.5.18, $\overline{\mathrm{x}}$ is not a genus zero or one system.

Lemma 2.5.20. Let $G$ be a finite group and $M$ a subgroup of $G$, then following hold

1. If $\left(\frac{1}{[G: M]}\right) \sum_{i=1}^{r} \sum_{j}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}<A(\bar{x})-2$, then $\bar{x}$ is not genus zero system,
2. If $\left(\frac{1}{[G: M]}\right) \sum_{i=1}^{r} \sum_{j}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}} \neq A(\bar{x})-2$ then $\bar{x}$ is not genus one system,
3. if $\left(\frac{1}{[G: M]}\right) \sum_{i=1}^{r} \sum_{j}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}>A(\bar{x})-2$. then $\bar{x}$ is not genus two system,

Proof. 1. Suppose that $\bar{x}$ is a genus zero system then by the Riemann Hurwitz formula

$$
\begin{aligned}
& \sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=2 n-2 . \text { Since } \\
& \qquad \begin{aligned}
& \operatorname{ind}\left(x_{i}\right)=n-\sum_{j=1}^{d_{i}} \frac{f\left(x_{i}^{j}\right)}{d_{i}} \\
= & n-\left(\sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}+\frac{f\left(x_{i}^{d_{i}}\right)}{d_{i}}\right) \\
& =n-\frac{n}{d_{i}}-\sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}
\end{aligned}
\end{aligned}
$$

So

$$
\operatorname{ind}\left(x_{i}\right)=n\left(\frac{d_{i}-1}{d_{i}}\right)-\sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}
$$

therefore we get

$$
\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=n \sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}-\sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}} .
$$

Finally, we get $\frac{1}{n} \sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}=A(\bar{x})-2+\frac{2}{n} \quad$ as $\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=2 n-2$.
Hence $\bar{x}$ is a genus zero system if and only if $\frac{1}{[G: M]} \sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}=A(\bar{x})-2+\frac{2}{n}$.
It is clear that $[G: M]=n \geqslant 1$. So if $\left(\frac{1}{[G: M]}\right) \sum_{i=1}^{r} \sum_{j}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}<A(\bar{x})-2$, then the Riemann Hurwitz formula fails. Hence the claim.
2. Suppose that $\bar{x}$ is a genus one system. Then by the Riemann Hurwitz formula $\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=$ $2 n$.

Similarly,

$$
2 n=\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=n \sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}-\sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}} .
$$

Thus

$$
\frac{1}{[G: M]} \sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}=A(\bar{x})-2
$$

In the other words if

$$
\frac{1}{[G: M]} \sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}} \neq A(\bar{x})-2
$$

then the Riemann Hurwitz formula fails. Hence $\bar{x}$ is not a genus one system
3. Suppose that $\bar{x}$ is a genus two system. Then by the Riemann Hurwitz formula $\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=$ $2 n+2$.

So

$$
\frac{1}{[G: M]} \sum_{i=1}^{r} \sum_{j=1}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}=A(\bar{x})-2-\frac{2}{n} .
$$

In the other words, $\bar{x}$ is not a genus two system, if

$$
\left(\frac{1}{[G: M]}\right) \sum_{i=1}^{r} \sum_{j}^{d_{i}-1} \frac{f\left(x_{i}^{j}\right)}{d_{i}}>A(\bar{x})-2 .
$$

Note that the above lemmas can be used to eliminate some systems, which are not of genus zero, one and two.

Lemma 2.5.21. Let $f: X \rightarrow Y$ be a Galois cover with group of deck transformation $G$ and let A,B be two proper subgroups of $G$. If $1_{A}^{G}$ is submodule of $1_{B}^{G}$, then $g(X / A) \leqslant g(X / B)$.

A complete proof of 2.5 .21 can be found in [11]. If $M_{1}$ and $M_{2}$ are non-conjugate maximal subgroups of the group $G$ affording permutation characters $\chi_{1}$ and $\chi_{2}$ respectively such that $\chi_{1}$ lies in $\chi_{2}$, then any systems eliminated as possible low genus systems in their action on the cosets of $M_{1}$, are also eliminated as potential low genus systems in their action on the cosets of $M_{2}$.

In this thesis we will determine all possible signatures of genus zero, one and two systems of sporadic simple groups. A series of filters will be used to eliminate signatures. Now we will present the main filters and typical arguments which we employ to eliminate signatures .

## CHAPTER 3

## Possible RAMIFICATION TYPES FOR THE

## Sporadic simple groups

The list of sporadic simple groups contains 26 groups. The Mathieu groups $M_{11}, M_{12}, M_{22}, M_{23}$ and $M_{24}$ were discovered by Mathieu $(1861,1873)$ [7]. They are the earliest sporadic simple groups to be discovered.

A Steiner system $S(t, k, v)$ is a finite set $X$ of $v$ points together with a set of $k$-element subset of $X$ (called blocks and denoted by $B$ ) with the property that every t-points of the set $X$ is contained in a unique block[8].

The automorphism group of the unique Steiner system $S(5,8,24)$ is $M_{24}$. The stabilizer of a point is the group $M_{23}$ of order $\left|M_{24}\right| / 24=10200960$. In fact $M_{23}$ is the group of automorphisms of the Steiner system $S(4,7,23)$. The group $M_{22}$ is the pointwise stabilizer in $M_{24}$ of two points. $M_{22}=\left|M_{23}\right| / 23=443520$. The pointwise stabilizer in $M_{24}$ of three points is the group $M_{21}$, of order $\left|M_{22}\right| / 22=20160$, and is isomorphic to the group $P S L_{3}(4)$ [7]. The Mathieu groups $M_{24}, M_{23}, M_{22}$ together are called the large Mathieu groups. Moreover, the automorphism of the group $M_{22}$ is a maximal subgroups of $M_{24}$. The embedding of the group $M_{22}: 2$ in the group $M_{24}$ has orbit shape 2+22[8].

A binary linear code $\mathscr{C}$ based on a finite set $A$ is a subspace of the power set $2^{A}$. The size of finite set $A$ is called length of linear code $\mathscr{C}$. A triple $(\mathscr{C}, A, V)$ is a linear code over $G F(q)$ where $V$ is a vector space over $G F(q), A$ is a basis of $V$ and $\mathscr{C}$ subspace in $V$. Moreover, the number of the elements of the smallest non-empty subset in the code $\mathscr{C}$ is called the minimal
weight of $\mathscr{C}$. If number of elements of every subset in $\mathscr{C}$ is even then the code is called even. The orthogonal complement of the code $\mathscr{C}$ with respect to the parity form

$$
\mathscr{C}^{*}=\left\{C\left|C \in 2^{A},|C \cap B| \text { is even for all } \mathrm{B} \in \mathscr{C}\right\}\right.
$$

is called dual code $\mathscr{C}^{*}$ of the code $\mathscr{C}$. The code $\mathscr{C}$ is called self-dual if $\mathscr{C}=\mathscr{C}^{*}$. A Golay code is a self-dual code $\varsigma$ of length 24 in which the minimal weight $\geqslant 8$.

The stabilizer in $M_{24}$ of one of a Golay code word of weight 12 , is the group $M \simeq M_{12}$ of order $\left|M_{24}\right| / 2576=9540$. This fact was discovered by Frobenius using character theory. It is also known that $N_{M_{24}}(M) \simeq \operatorname{Aut}\left(M_{12}\right) . M_{12}$ has a natural permutation representation of degree 12 . The point sets in $M_{12}$ in it degree 12 action is the smallest Mathieu group $M_{11}$. It's sharply 4-transitive permutation group on 11 points. Furthermore, the group $M_{11}$ is one of the maximal subgroup of $M_{23}$.

The Janko groups $J_{1}, J_{2}, J_{3}$ and $J_{4}$ were discovered in $(1965,1975)$ [7]. The smallest Janko group $J_{1}$ was discovered by Zvonimir Janko around one hundred years after the first Mathieu group was discovered.[20]. The story of discovering of the smallest Janko group $J_{1}$ begins with the centralizer involution of group of the Ree group of Lie type. It was shown that if $a$ is an involution of the Ree group $G$ then $C_{G}(a)$ is isomorphic to external direct product $Z_{2} \times P S L_{2}\left(3^{n}\right)$ and the Sylow 2-subgroups are elementary abelian groups of order eight. Conversely it has been established that all simple groups with Sylow 2-subgroup of order eight which have centralizer involution isomorphic to $Z_{2} \times P S L_{2}\left(p^{n}\right), p$ and odd prime then $p=3, n=2 r+1$ or $p^{n}=5$. Janko showed that if $G$ is a simple group such that $G$ has elementary abilean Sylow 2-subgroups of order 8 and if $a$ is an involution in $G$ with $C(a) \cong Z_{2} \times P S L_{2}$ (5), then $G$ is isomorphic to smallest Janko group $J_{1}[20]$. The group $J_{1}$ has a trivial outer automorphism. Z. Janko in [20] indicated that there are two new simple groups in which $2^{1+4}: A_{5}$ is a centralizer of an involution. These two new simple group are $J_{2}$ and $J_{3}$. The Janko group $J_{2}$ was found by M.Hall and D.Wales (1967) as a rank 3 permutation group on 100 points [16]. The group $J_{2}$ has non trivial outer automorphism and it is the only one of the four Janko groups that is involved in the Monster group. The Janko group $J_{3}$ was constructed by G.Higman and J.Mckay in 1969 [18]. Similarly, the largest Janko group $J_{4}$ was constructed during the proof
of the classification theorem of finite simple group. It was discovered by Z. Janko by looking for groups with an involution centralizer of the form $2^{1+12} .3 .\left(M_{22}: 2\right)$ [21]. He showed that if a simple group $G$ exists with involution centralizer of the form $2^{1+12} .3 .\left(M_{22}: 2\right)$ then $G$ contains a subgroup of the form $2^{11}: M_{24}$. By this time, much of the proofs of the classification theorem of finite group had been completed however, studying groups with an involution centralizer remind[38]. The group $J_{4}$ has trivial outer automorphism and it is not involved in the Monster group.

A non empty set $L$ is said to be a lattice if $L$ is a finitely generated free Z-module with an integer valued bilinear form, written $(a, b)$ for $a, b \in L[4]$. The lattice is said to be integral if $(a, b)$ takes integer value. An integral lattice $L$ is said to be a unimodular lattice if it is of determinate 1 or -1. The even unimodular lattice in 24-dimension Euclidean space is said to be a Leech lattice[4].

The Conway groups $\mathrm{Co}_{1}, \mathrm{Co}_{2}, \mathrm{Co}_{3}$ can be derived from the Leech lattice. The largest Conway group $\mathrm{Co}_{1}$ is the automorphism group of Leech lattice, modulo a center of order two, which was discovered by J.H Conway[7]. The outer automorphism group of the group $C o_{1}$ is trivial. By reducing modulo 2 and factoring out a fixed vector we get the group $\mathrm{Co}_{2}$ which is maximal subgroup of the group $\mathrm{Co}_{1}$. The group $\mathrm{Co}_{3}$ is occurred as a subgroup of automorphism Leech lattice fixing a vector of "type 3 ". Based in the fact that the $\mathrm{Co}_{3}$ is maximal subgroup in the largest Conway group $\mathrm{Co}_{1}$, the group $\mathrm{Co}_{3}$ has 2-transitive action of degree 276. The single point stabilizer of $\mathrm{Co}_{3}$ of this action is the automorphism group of the McLaughlin group $(M c L)$. The group ( $M c L$ ) was found by McLaughlin as a permutation group acting on the McLaughlin graph with $275=1+112+162$ vertices [7]. The group Higman-Sims $(H S)$ is a maximal subgroup of the group $\mathrm{Co}_{3}$ which is discovered by Donald G. Higman and Charles C. Sims [7]. They derived their groups as a rank 3 primitive permutation group of degree 100. The Suzuki (Suz) group was found by M.Suzuki [7]. It also can be obtained from the Leech lattice. B. Fischer- R.L. Griess- M.P.Thorne, using the existence of $\mathrm{Co}_{1}$ predicted the existent of a simple group with involution centralizer $2^{1+24} . \mathrm{Co}_{1}$ (where $2^{1+24}$ denotes an extra special group of order $2^{25}$ ) and constructed its character table. In 1980 R.L. Griess showed that this group exists and can be shown to be the automorphism group of a 196884 dimensional algebra. This is called the monster group. 20 of the sporadic simple group are involved in the Monster. The
remaining six are called pariahs.
The Fischer groups $F i_{22}, F i_{23}$ and $F i_{24}$ are another list of the sporadic groups. They are subquotients of the Monster group. Fisher's Theorem[9] classified 3-transposition groups (a group generated by a conjugacy class of involution in which the product of any two non-commutative involutions has order three). The Fisher groups are special cases of Fisher Theorem. Further, the Fisher groups $F i_{22}, F i_{24}$ has non-trivial outer automorphisms.

Dieter Held in paper [17] was looking for the simple groups with the property, that this simple group containing an involution $z$ such that centralizer of $z$ is isomorphic to that of an involution in the group $M_{24}$. During his investigation he obtained the group Held ( He ). The group Rudvalis (Ru), Harada-Norton (HN), Thompson (Th), Baby Monster (B), O'Nan (ON), and Lyons ( $L y$ ), are the large sporadic simple groups.

In this thesis we will compute braid orbits of Nielsen class of sporadic almost simple groups. Recall that a function $f$ is indecomposable if $f$ can not be written as a composition of two functions of degree greater than one. In our work we are interested in the structure of the monodromy group $G$ of $f$ when $X$ is a compact Riemann surface of genus $g \leqslant 2$ and $f$ is indecomposable meromorphic function. We recall that the monodromy group is primitive in its monodromy action on the fiber over the base point if and only if the corresponding cover of it is indecomposable. In light of this statement we are interested in finding all equivalence classes of admissible generating tuples for sporadic simple groups when the genus of the cover is 0,1 or 2 . Recall definition genus $g$-system is defined as follows.

Definition 3.0.22. Assume that $G$ is a transitive group of $S_{n}$. A genus $g$ - system is a tuple $\bar{x}=\left(x_{1}, x_{2}, \cdots, x_{r}\right)$ such that for all $1 \neq x_{i} \in G, 1 \leqslant i \leqslant r, x_{1}, \cdots x_{r}=1$ and $G=\left\langle x_{i} \mid 1 \leqslant i \leqslant r\right\rangle$ and

$$
\begin{equation*}
\sum_{i=1}^{r} \operatorname{ind}\left(x_{i}\right)=2(n+g-1) . \tag{1}
\end{equation*}
$$

If $G$ acts primitively, then the genus $g$ system is called a primitive genus $g$ system. Furthermore, a primitive genus $g$ system is called a primitive low genus system if $g \leqslant 2$.

The small sporadic simple groups possess primitive permutation representation of degree $\leq 2500$ and these are stored, for example, in GAP.

We use the function AllPrimitiveGroups(DegreeOperation,n) to retrieve a copy of a sporadic simple group, which acts primitively on n points. We present the code and explain the following example.

Example 3.0.23. gap> AllPrimitiveGroups(DegreeOperation,11);
$[\mathrm{C}(11), \mathrm{D}(2 * 11), 11: 5, \operatorname{AGL}(1,11), \mathrm{L}(2,11), \mathrm{M}(11), \mathrm{A}(11), \mathrm{S}(11)]$
gap $>\mathrm{k}:=$ last [6];
M(11)

Here we retrieve the sporadic Mathieu group $M_{11}$ in its action on 11 points.
Each sporadic simple groups has several conjugacy classes of maximal subgroups. We record the number of conjugacy classes of maximal subgroups in the following table

Table 3.1: Number of classes of maximal subgroups of sporadic simple groups

| Groups | No. Maximal Subgroups | Groups | No.Maximal Subgroups | Groups | No.Maximal Subgroups |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $M_{11}$ | 5 | $M_{12}$ | 7 | $M_{22}$ | 7 |
| $M_{23}$ | 6 | $M_{24}$ | 9 | $J_{1}$ | 7 |
| $J_{2}$ | 9 | $J_{3}$ | 8 | $J_{4}$ | 11 |
| $C o_{1}$ | 24 | $C o_{2}$ | 11 | $C o_{3}$ | 14 |
| $F i_{22}$ | 14 | $F i_{23}$ | 14 | $F i_{24}$ | 20 |
| $S u z$ | 17 | $H S$ | 11 | $M c L$ | 12 |
| $H e$ | 11 | $H N$ | 14 | $T h$ | 15 |
| $B$ | 28 | $O N$ | 9 | $L y$ | 9 |
| $R u$ | 15 | $M$ | unknown |  |  |

The GAP library stores primitive permutation groups of degree up to 2500 but some sporadic simple groups only have maximal subgroups of index more than 2500 . Sometime it is convenient for us to construct permutation representations of such group of large degree. We explain how we do this via the following example.

Example 3.0.24. The smallest maximal subgroups of the Janko group $J_{2}$ are isomorphic to $A_{5}$. The degree of operation of $G$ of this class $A_{5}$ is 10080 as $10080=|J 2| /|A 5|$. Also, there are up to conjugacy 3 distinct embeddings of $A 5$ into $J_{2}$.

In GAP we can proceed as follows:

- Get $J_{2}$ and $A_{5}$ as follows

```
gap>J2 := UnderlyingGroup(TableOfMarks("J2"));
<permutation group of size 604800 with 2 generators>
gap> A5 := AlternatingGroup(5);
```

Alt ( [ 1 .. 5 ] )

- Find the embeddings of $A_{5}$ into $J_{2}$ up to conjugacy.
gap> embs := IsomorphicSubgroups(J2,A5);;
gap> acts := List(embs,phi->Action(J2,RightCosets(J2,Image(phi)),OnRight));
<permutation group with 2 generators>, <permutation group with 2 generators>,
<permutation group with 2 generators>
- Check which are maximal

```
gap> for i in[1..Length(act)] do
> if Order(act[i])= Order(J2) then
> if IsPrimitive(act[i]) then Print(i)
> fi;fi;od;
3
```

- Finally, find all conjugacy class representative then find indices of representative

```
gap> cclreps := List(acts[3],G->List(ConjugacyClasses(G),Representative));;
gap> indices := List(cclreps,reps->List(reps,
g->10080-Length (Orbits(Group(g),[1..10080]))));
[0, 5010, 6720, 8390, 6480, 8064, 8064, 9360, 9360, 8640, 9066, 9066,
5040, 7560, 8820, 8280, 9180, 8056, 8056, 9068, 9068]
gap>ll := [];
[];
gap>for i in [1..Length(acts)] do
>ll[i] := [];
>for j in [2..Length(cclreps[i])] do
>Add(ll[i],rec(pos:=j,index:=indices[i][j],ord:=Order(cclreps[i][j])));
od;
od;
```

### 3.1 Possible Ramification Types

In this section we aim to determine all possible ramification types for sporadic simple groups of genus zero, one and two. Recall that Ree's theorem states that, if $G$ is a transitive group on a set of size $n$ and $x_{1}, x_{2}, \cdots, x_{r}$ are permutations generating $G$ with $x_{1} . x_{2} \cdots, x_{r}=1$, then $O_{1}+$ $O_{2}+\cdots+O_{r} \leqslant(r-2) n+2$ where $O_{i}$ is the number of orbits $\left\langle x_{i}\right\rangle$. In the light of Ree's theorem we can expect to eliminate certain potential ramification types from further consideration.

In our work we use the Riemann Hurwitz formula( equation 1) to identify the possible ramification types. It should be noted that the right side of Riemann Hurwitz formula (1), is easy to compute. To find left side of the Riemann Hurwitz formula we first, by using GAP compute all conjugacy class representatives of the groups. Next we compute the index for each conjugacy class representative on every type primitive permutation representation. We define a tuple, which is a list of permutation indices such that the sum is equal the right hand side of the Riemann Hurwitz formula. We will explain this using the following example

Example 3.1.1. gap> AllPrimitiveGroups(DegreeOperation,11); ;

```
[ C(11), D(2*11), 11:5, AGL(1, 11), L(2, 11), M(11), A(11), S(11) ]
gap> k:=last[6];
gap> reps:=List(ConjugacyClasses(k), x->Representative(x));;
gap> Ind:=List(reps,x->11-Length(Orbits(Group(x),[1..11])));
[0,8,4,6,8,8,6,8,10,10]
11:=[];
[]
gap> for i in [2..Length(reps)] do
> Append(ll,[rec(pos:=i,index:=Ind[i],ord:=Order(reps[i]))]);
> od;
gap>ll;
[rec( index := 8, ord := 5, pos := 2 ), rec( index := 4, ord := 2, pos := 3
), rec( index := 6, ord := 4, pos := 4 ), rec( index := 8, ord := 8, pos :=
5 ), rec( index := 8, ord := 8, pos := 6 ), rec( index := 6, ord := 3, pos
```

$:=7$ ), rec $($ index $:=8$, ord $:=6, \operatorname{pos}:=8), \operatorname{rec}($ index $:=10$, ord $:=11$,
pos $:=9$ ), rec( index $:=10$, ord $:=11$, pos $:=10$ )]
indes:=List(ll, $x->x . i n d e x)$;
tuple:=RestrictedPartitions(20,indes);
$[4,8,8],[4,4,4,8],[4,4,4,4,4],[6,6,8],[6,6,4,4],[8,4,8],[8,4,4,4],[8,6,6],[8,8,4],[8,4,8],[8,4,4,4]$,
$[8,6,6],[8,8,4],[8,8,4],[6,6,8],[6,6,4,4],[6,8,6],[6,8,6],[6,6,8],[6,6,4,4],[6,6,8],[6,6,8],[8,4,8]$,
$[8,4,4,4],[8,6,6],[8,8,4],[8,8,4],[8,6,6],[8,6,6],[8,8,4],[10,6,4],[10,6,4],[10,10],[10,6,4]$, $[10,6,4],[10,10],[10,10]]$

Now, we present the number of ramification types for the sporadic simple groups of genus zero, one and two system which satisfy Riemann Hurwitz formula 1.

Table 3.2: Possible ramification type of Mathieu groups

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $M_{11}$ | 79 | 109 | 155 | 343 |
| $M_{12}$ | 154 | 256 | 342 | 752 |
| $M_{12}: 2$ | 16 | 27 | 7 | 50 |
| $M_{22}$ | 34 | 43 | 58 | 135 |
| $M_{22}: 2$ | 177 | 214 | 255 | 646 |
| $M_{23}$ | 54 | 55 | 93 | 202 |
| $M_{24}$ | 162 | 264 | 308 | 734 |

For some large sporadic simple groups we will prove later that they have no ramification

Table 3.3: Possible ramification type of Janko groups

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $J_{1}$ | 1 | 0 | 0 | 1 |
| $J_{2}$ | 21 | 45 | 32 | 98 |
| $J_{2}: 2$ | 39 | 51 | 47 | 137 |
| $J_{3}$ | we will prove that it has no ramification type |  |  |  |
| $J_{4}$ | we will prove that it has no ramification type |  |  |  |

Table 3.4: Possible ramification type of Conway groups

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Co}_{3}$ | 15 | 16 | 19 | 50 |
| $\mathrm{Co}_{2}$ | 6 | 4 | 5 | 15 |
| $\mathrm{Co}_{2}: 2$ | 0 | 1 | 0 | 1 |
| $\mathrm{Co} o_{1}$ | 5 | 1 | 0 | 6 |

Table 3.5: Possible ramification type of Large Sporadic groups

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $H S$ | 35 | 49 | 27 | 111 |
| $H S: 2$ | 86 | 109 | 106 | 301 |
| $M c L$ | 5 | 6 | 3 | 14 |
| $M c L: 2$ | 6 | 10 | 11 | 27 |
| $S u z$ | 1 | 10 | 0 | 11 |
| $S u z: 2$ | 2 | 9 | 3 | 14 |
| $H e$ | 0 | 7 | 1 | 8 |
| $H e: 2$ | 0 | 8 | 1 | 9 |
| $F i_{22}$ | 2 | 12 | 1 | 15 |
| $F i_{2} 2: 2$ | 4 | 18 | 13 | 25 |
| $F i_{23}$ | 0 | 1 | 0 | 1 |
| $F i_{24}$ | we will prove that it has not ramification type |  |  |  |
| $O N$ | we will prove that it has no ramification type |  |  |  |
| $T h$ | we will prove that it has no ramification type |  |  |  |
| $L y$ | we will prove that it has no ramification type |  |  |  |
| $R u$ | we will prove that it has no ramification type |  |  |  |
| $B$ | we will prove that it has no ramification type |  |  |  |
| $M$ | we will prove that it has no ramification type |  |  |  |

In lower case next step we eliminate ramification types by using the filters that we presented in the previous chapter. We also present some additional filters.

### 3.1.1 The ClassStructureCharacterTable function

Let $G$ be a group and $\left(g_{1}, g_{2}, \ldots, g_{r}\right)$ be a r-tuple in $G$ with $g_{1} . g_{2} \cdots g_{r}=1$. Let $C_{1}, C_{2}, \ldots, C_{r}$ conjugacy class of the group $G$ such that $g_{i}$ is in $C_{i}$ then the number of r-tuples $\left(g_{1}, g_{2}, \ldots, g_{r}\right)$ is computed by this formula

$$
\begin{equation*}
N\left(C_{1}, C_{2}, \ldots, C_{r}\right)=\frac{\left|C_{1}\right|\left|C_{2}\right| \ldots\left|C_{r}\right|}{|G|} \sum \frac{\chi\left(g_{1}\right) \chi\left(g_{2}\right) \ldots \chi\left(g_{r}\right)}{\chi(1)^{r-2}} \tag{2}
\end{equation*}
$$

We use the function ClassstructureCharacterTable to compute the value $N\left(C_{1}, C_{2}, \ldots, C_{r}\right)$ for the tuples surviving the first filters. If the group algebra structure constant of any tuple is equal to zero then we remove this tuple from our candidate list. For example the Mathieu group $M_{12}$ not of type $(2,3,10)$ and $(2,2,2,3)$ because a GAP calculation shows that structure constants of $(2,3,10)$ and $(2,2,2,3)$ are equal to zero. Thus these cases do not need to be considered.

### 3.1.2 Generating Group Criterion

Recall that the symmetric genus of a finite group $G$ is the smallest integer $g$ such that $G$ acts faithfully as automorphisms of an oriented a closed orientable surface $S_{g(G)}$ of genus $g(G)$. The symmetric genus of $G$ can be calculated by using the formula $g(G)=\frac{|G|}{2}(N-2)+1$, where

$$
N=\min _{\bar{x}}\left\{A(\bar{d}) \mid \bar{d}=\operatorname{signature}(\bar{x}), G=\langle\bar{x}\rangle, \prod_{\bar{x}} x_{i}=1\right\} .
$$

Using the GAP program, it is a straightforward exercise to calculate for all triples $(x, y, z)$ within $G$ such that $x \cdot y=z^{-1}$. In other words, if any triple $(x, y, z) \in G$ does not satisfy $x \cdot y \cdot z=1$ it will be eliminated. Moreover, if the triple $(x, y, z)$ passes this step, the second step we will examine the order of the group generated by pair $(x, y)$, if it does not equal to the order of group $G$, then we will ignore the triple $(x, y, z)$. By using the following program we obtain above results
gap> AllPrimitiveGroups(DegreeOperation,11);
gap $>\mathrm{k}:=$ last [6] ;
gap $>$ reps:=List(ConjugacyClasses(k), $x->$ Representative( x )); ;
gap> ind:=List(reps,x-> NrMovedPoints(k) -
Length (Orbits(Group (x), [1..NrMovedPoints(k)]))); ;
gap> elts2:=Elements(ConjugacyClass(k,reps[a])); ;
gap> ff:=Filtered(elts2,x-> IsConjugate (k, x*reps[b],reps[c] $\left.{ }^{-1}\right)$ ); ;
gap> fff:=Filtered(ff,x-> Size(Group(x,reps[b])) = Size(k)); ;
gap> Length(fff);
We call this criterion the generating group criteria.

### 3.2 The ramification types of Mathieu groups

In this section we eliminate some ramification types of Mathieu groups by using the series of filters which were mentioned in the previous chapter and in the section 3.1.

### 3.2.1 The Mathieu group $M_{11}$

The smallest Mathieu group $M_{11}$ is of order 7920. The classes of maximal subgroups of $M_{11}$ are given in the first row of the following table.

| Maximal subgroups | $M_{10}$ | $L_{2}(11)$ | $M_{9}: 2$ | $S_{5}$ | $M_{8}: S_{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Index in G | 11 | 12 | 55 | 66 | 165 |
| N.R.T | 165 | 150 | 14 | 12 | 2 |

The Riemann Hurwitz formula implies that the Mathieu group $M_{11}$ has 343 ramification types. The details are given in the third row of the above table. By using the Zariski condition we can eliminate three ramification types of $G$ in its action on the first maximal subgroups and one ramification type in its action on the third maximal subgroup.

Lemma 3.2.1. Let $G$ be the Mathieu group $M_{11}$ and $\bar{x}=\left(x_{1}, \cdots x_{r}\right) \in G^{r}$. Then $\bar{x}$ is not a genus zero, one and two-system if $A(\overline{\mathrm{x}})<\frac{95}{44}$, where $A(\overline{\mathrm{x}})=\sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}$.

Proof. By Theorem 2.5.10 the minimal genus action is achieved by the ramification type (2,4,11)generation of $M_{11}$. This means that if $A(\overline{\mathrm{x}})<\frac{1}{2}+\frac{3}{4}+\frac{10}{11}=\frac{95}{44}$, then $M_{11}$ is not a genus zero, one and two-group.

By using Lemma 3.2.1 we eliminate 5,2 resp 6 ramification types of $G$ in its action on the 1st, 2nd resp 3rd maximal subgroup. Next, by using generating group criteria we check that $G$ is not of type $(2,6,6)$. Indeed given an element $z$ of order six, there are conjugacy classes of pairs $(x, y)$ of order two and six such that $x y=z^{-1}$. However, the order of the groups which are generated by conjugacy classes of the pair $(x, y)$ are not equal to the order of the group $M_{11}$. It follows that the triple $(2,6,6)$ can be eliminated. Using similar considerations we eliminate 11 ramification types of first maximal subgroup, 7 ramification types of second maximal subgroup and 5 ramification types of third maximal subgroup. Finally, by using Lemma 2.5.21, we eliminate 10 ramification types of the maximal subgroup $S_{5}$ and two ramification types of maximal subgroup $M_{8}: S_{3}$. The final list of ramification types which survive the filters is presented in the following table.

| Maximal subgroups | $M_{10}$ | $L_{2}(11)$ | $M_{9}: 2$ | $S_{5}$ | $M_{8}: S_{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 11 | 12 | 55 | 66 | 165 |
| N.R.T | 146 | 141 | 2 | 2 | 0 |

### 3.2.2 The Mathieu group $M_{12}$ and its Automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=M_{12}$. The Mathieu group $M_{12}$ has eight classes of maximal subgroups which are given in the first row in the Table 3.6. The indexes and number of ramification types are give in rows two and three respectively.

Table 3.6:

| Maximal subgroups | $M_{11}$ | $M_{10}: 2$ | $L_{2}(11)$ | $M_{9}: S_{3}$ | $2 \times S_{5}$ | $M_{8}: S_{4}$ | $4^{2}: D_{12}$ | $A_{4} \times S_{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 12 | 66 | 144 | 220 | 396 | 495 | 495 | 1320 |
| N.R.T | 648 | 62 | 17 | 8 | 5 | 7 | 5 | 0 |

Lemma 3.2.2. Assume that $G$ is the Mathieu group $M_{12}$ and $\left(x_{1}, x_{2}, \cdots, x_{r}\right) \in G^{r}$. Then $\bar{x}=$ $\left(x_{1}, \cdots x_{r}\right)$ is not genus zero, one and two-system if $A(\overline{\mathrm{x}})<\frac{31}{15}$, where $A(\overline{\mathrm{x}})=\sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}$.

Proof. This follows from the Theorem 2.5.10. Since the Mathieu group $M_{12}$ can be generated by a triple of elements of order 2, 3 and 10 [6], which means that if $A(\overline{\mathrm{x}})<\frac{1}{2}+\frac{2}{3}+\frac{9}{10}=\frac{31}{15}$, then $M_{12}$ is not genus zero, one and two-system.

A GAP calculation shows that the group algebra structure constant of 20 ramification types of the first maximal subgroup, 9 ramification types of the second maximal subgroup and 2 ramification types of the fourth maximal subgroup in the Table3.6 above are equal to zero. Thus, all of these can not occur. By using the Zariski condition and Lemma 3.2.2 above we can eliminate $32,16,2$ respectively 5 ramification types of $G$ in its action on the 1 st, 2nd, 3 rd respectively 4th maximal subgroup. Assume that $x, y$ and $z$ are representatives of the conjugacy class of elements of order four. So if $x, y$ are conjugacy classes in the same type or in different type then there are conjugacy classes of pairs $(x, y)$ whose product is equal to $z^{-1}$. In both cases the order of the group $\langle x, y\rangle$ is different form the order of the Mathieu group $M_{12}$. Thus $G$ is not of type $(4,4,4)$. Using similar considerations we eliminate a further 27 ramification types of the first maximal subgroups, 24 ramification types of the second maximal subgroup and 12 ramification types of the third maximal subgroup. Finally by using Lemma 2.5.21 all
ramification types of the maximal subgroups $2 \times S_{5}, M_{8}: S_{4}, 4^{2}: D_{12}$ are eliminated. So, the final list of ramification types which passed the filters we present in the following table.

Table 3.7:

| Maximal subgroups | $M_{11}$ | $M_{10}: 2$ | $L_{2}(11)$ | $M_{9}: S_{3}$ | $2 \times S_{5}$ | $M_{8}: S_{4}$ | $4^{2}: D_{12}$ | $A_{4} \times S_{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 12 | 66 | 144 | 220 | 396 | 495 | 495 | 1320 |
| N.R.T | 569 | 13 | 3 | 1 | 0 | 0 | 0 | 0 |

Now we will describe an analysis of $\operatorname{Aut}\left(M_{12}\right)$ similar to the one above. Let $G$ be the almost simple group $\operatorname{Aut}\left(M_{12}\right)=M_{12}: 2$. The classes of maximal subgroups of $G$, their indexes, and number of ramification types is presented in the following table.

Table 3.8:

| Maximal subgroups | $L_{2}(11): 2$ | $\left(2^{2} \times A_{5}\right): 2$ | $H .2$ | $H .2$ | $S_{4} \times S_{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 144 | 396 | 495 | 495 | 1320 |
| N.R.T | 56 | 9 | 6 | 3 | 0 |

Similarly, by using the Zariski condition, the ClassStructureCharacterTable function and the Generating group criterion all but eight ramification types in the first maximal subgroup in Table 3.8 can be eliminated .

### 3.2.3 The Mathieu group $M_{22}$ and its Automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=M_{22}$. The Mathieu group $M_{22}$ has seven classes of maximal subgroups which are shown in the first row in Table 3.9. The indexes and number of ramification types, which are satisfying the Riemann-Hurwitz formula for $g=0,1$ or 2 are given in the rows two and three respectively.

Table 3.9:

| Maximal subgroups | $L_{3}(4)$ | $2^{4}: A_{6}$ | $A_{7}$ | $2^{4}: S_{5}$ | $2^{3}: L_{2}(3)$ | $M_{10}$ | $L_{2}(11)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 22 | 77 | 176 | 231 | 330 | 616 | 672 |
| N.R.T | 104 | 19 | 5 | 3 | 2 | 2 | 0 |

Lemma 3.2.3. Assume that $G$ is the Mathieu group $M_{22}$ and $\left(x_{1}, x_{2}, \cdots, x_{r}\right) \in G^{r}$. Then $\bar{x}=$ $\left(x_{1}, \cdots x_{r}\right)$ is not genus zero, one and two-system if $A(\overline{\mathrm{x}})<\frac{151}{70}$, where $A(\overline{\mathrm{x}})=\sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}$.

The number of ramification types additionally satisfying the condition of Lemma 3.2.3 and the Zariski condition is shown below

| Maximal subgroups | $L_{3}(4)$ | $2^{4}: A_{6}$ | $A_{7}$ | $2^{4}: S_{5}$ | $2^{3}: L_{2}(3)$ | $M_{10}$ | $L_{2}(11)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| N.R.T | 104 | 14 | 1 | 1 | 0 | 0 | 0 |

One can check in GAP that two elements $x, y$ of order 4, in the same class or in different type such that $x y$ is also of order 4 never generate the whole group $M_{22}$. Thus $G$ is not of type $(4,4,4)$. In a similar way two , eight,one respectively one ramification type in its action on the 1st, 2nd resp 3rd and 4th maximal subgroup can be canceled. So the final list of ramification types is presented in the following table

| Maximal subgroups | $L_{3}(4)$ | $2^{4}: A_{6}$ | $A_{7}$ | $2^{4}: S_{5}$ | $2^{3}: L_{2}(3)$ | $M_{10}$ | $L_{2}(11)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 22 | 77 | 176 | 231 | 330 | 616 | 672 |
| N.R.T | 102 | 6 | 0 | 0 | 0 | 0 | 0 |

Now we will do the similar analysis for the automorphism group of $M_{22}$. Let $G$ be the almost simple group $\operatorname{Aut}\left(M_{22}\right)$. The classes of maximal subgroups of $G$, their indexes and the number of ramification types is presented in the following table.

Table 3.10:

| Maximal subgroups | $L_{3}(4): 2_{2}$ | $2^{4}: S_{6}$ | $2^{5}: S_{5}$ | $2^{3}: L_{2}(3) \times 2$ | $A_{6} \cdot 2^{2}$ | $L_{2}(11): 2$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 22 | 77 | 231 | 330 | 616 | 672 |
| N.R.T | 413 | 157 | 38 | 35 | 2 | 1 |

By using the generating group criterion 121 ramification types of the first maximal subgroup in the Table 3.10 can be ruled out. Lemma 2.5.21 implies that 133 ramification types of the second maximal subgroup and all ramification types of the other maximal subgroups can be ruled out. So the final result is presented in the following table.

| Maximal subgroups | $L_{3}(4): 2_{2}$ | $2^{4}: S_{6}$ | $2^{5}: S_{5}$ | $2^{3}: L_{2}(3) \times 2$ | $A_{6} \cdot 2^{2}$ | $L_{2}(11): 2$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| N.R.T | 291 | 24 | 0 | 0 | 0 | 0 |

### 3.2.4 The Mathieu group $M_{23}$

Let $G$ be a Mathieu group $M_{23}$. The classes of maximal subgroups of $M_{23}$, their indexes and number of ramification types are given in the following table.

| Maximal subgroups | $M_{22}$ | $L_{3}(4): 2_{2}$ | $2^{4}: A_{7}$ | $A_{8}$ | $M_{11}$ | $2^{4}:\left(3 \times A_{5}\right): 2$ | $23: 11$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 23 | 253 | 253 | 506 | 1288 | 1771 | 40320 |
| N.R.T | 182 | 10 | 10 | 0 | 0 | 0 | 0 |

Lemma 3.2.4. Assume that $G$ is the Mathieu group $M_{23}$ and $\left(x_{1}, x_{2}, \cdots, x_{r}\right) \in G^{r}$. Then $\bar{x}=$ $\left(x_{1}, \cdots x_{r}\right)$ is not genus zero, one and two-system if $A(\overline{\mathrm{x}})<\frac{203}{92}$, where $A(\overline{\mathrm{x}})=\sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}$.

Proof. Similarly, by Theorem 2.5.10.

Lemma 3.2.4 guarantees us that 4 ramification types of the first maximal subgroup and all ramification types of the second and third maximal subgroup can be ruled out.

### 3.2.5 The Mathieu group $M_{24}$

The largest Mathieu group $M_{24}$ is of order 244823040. Table 3.11 gives information about the classes of maximal subgroups of $M_{24}$.

Table 3.11:

| Maximal subgroups | $M_{23}$ | $M_{22}: 2$ | $2^{4}: A_{8}$ | $M_{12}: 2$ | $2^{6}:\left(3 . S_{6}\right)$ | $L_{3}(4): S_{3}$ | $\left.2^{6}:\left(L_{( } 3\right) \times S_{3}\right)$ | $L_{2}(12)$ | $L_{2}(7)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 24 | 276 | 759 | 1288 | 1771 | 2024 | 3795 | 40320 | 1457280 |
| b | $\frac{8}{24}$ | $\frac{36}{276}$ | $\frac{70}{759}$ | $\frac{56}{1288}$ | $\frac{91}{1771}$ | $\frac{120}{2024}$ | $\frac{99}{3795}$ | $\frac{320}{40320}$ | $\frac{960}{1457280}$ |

The maximal fixed point ratios in the respective actions are given in row three and the indexes of classes of maximal subgroups are given in row two in above table.

Lemma 2.5.19 implies that if $b+\frac{1}{[G: M]}<\frac{1}{85}$, then no genus system $\overline{\mathrm{x}}=\left(x_{1}, x_{2}, \ldots, x_{r}\right)$ satisfies the Riemann Hurwitz formula. So the group $M_{24}$ possesses no primitive genus zero, one and two systems in its action on the right cosets of the maximal subgroup $L_{2}(12)$ and $L_{2}(7)$. Next we present number of possible ramification types of the other maximal subgroups of $M_{24}$.

Table 3.12:

| Maximal subgroups | $M_{23}$ | $M_{22}: 2$ | $2^{4}: A_{8}$ | $M_{12}: 2$ | $2^{6}:\left(3 . S_{6}\right)$ | $L_{3}(4): S_{3}$ | $\left.2^{6}:\left(L_{( }\right) \times S_{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 24 | 276 | 759 | 1288 | 1771 | 2024 | 3795 |
| N.R.T | 697 | 21 | 6 | 6 | 0 | 4 | 0 |

Lemma 3.2.5. Assume that $G$ is the Mathieu group $M_{24}$ and $\left(x_{1}, x_{2}, \cdots, x_{r}\right) \in G^{r}$. Then $\overline{\mathrm{x}}=$ $\left(x_{1}, \cdots x_{r}\right)$ is not genus zero, one and two-system if $A(\overline{\mathrm{x}})<\frac{25}{12}$, where $A(\overline{\mathrm{x}})=\sum_{i=1}^{r} \frac{d_{i}-1}{d_{i}}$.

Proof. This follows from Theorem 2.5.10.

Lemma 3.2.5 guarantees that 17 of the 697 ramification type of the group $M_{24}$ acting on the cosets of $M_{23}$ can not occur. Now by using the Generating Group Criterion, if $x, y$ and $z$ are representatives of conjugacy classes $3 A, 4 A$ and $4 C$ respectively then there are conjugacy classes of pairs $(x, y)$ whose product is equal to $z$. However the order of the group $\langle x, y\rangle$ is not equal to order of the group $M_{24}$. Hence $G$ is not of type ( $3 A, 4 A, 4 C$ ). Similarly, 46 ramification type of the first maximal subgroup can be ruled out. All ramification types of other maximal subgroups are ruled out by Lemma 2.5.21.

### 3.3 The ramification types of Janko groups

In this section we will use series of filters to eliminate some ramification types of Janko groups.
Lemma 3.3.1. Let $G$ be the Janko group $J_{1}$. Then $G$ is (2,3,7)-generated.

Proof. A complete proof can be found in [39].
Lemma 3.3.2. Let $G$ be the Janko group $J_{2}$. Then $G$ is $(2,3,7)$-generated.

Proof. See [39].
Lemma 3.3.3. Let $G$ be the Janko group $J_{3}$. Then $G$ is (2,3,10)-generated.

Proof. See [39].

### 3.3.1 The Janko group $J_{1}$

The smallest Jonko group $J_{1}$ is of order 175560. The classes of maximal subgroups of $J_{1}$, their indexes and their maximal fixed point ratios in the representative action are given in the
following table.

Table 3.13:

| Maximal subgroups | $L_{2}(11)$ | $2^{3}: 7: 3$ | $2 \times A_{5}$ | $19: 6$ | $11: 10$ | $D_{6} \times D_{10}$ | $7: 6$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 266 | 1045 | 1463 | 1540 | 1596 | 2926 | 4180 |
| b | $\frac{10}{266}$ | $\frac{10}{1045}$ | $\frac{31}{1463}$ | $\frac{20}{1540}$ | $\frac{12}{1596}$ | $\frac{46}{2926}$ | $\frac{20}{4180}$ |

In ATLAS explain that the group $\mathrm{A}: \mathrm{B}$ denotes any group having a normal subgroup of structure A for which corresponding quotient group has structure B which is a split extension or semi direct product. Let M be one of the class of maximal subgroup $2^{3}: 7: 3,11: 10$ or $7: 6$, then $b+\frac{1}{[G: M]}<\frac{1}{85}$. Using Lemma 2.5.19 implies that the group $J_{1}$ possesses no primitive genus zero, one and two system in its action on the right cosets of the maximal subgroups $2^{3}: 7: 3$, 11:10 and 7: 6. Riemann Hurwitz formula implies that the maximal subgroup $2 \times A_{5}$ has one ramification type $(3 A, 3 A, 3 A)$ which is eliminated by the Zariski condtion.

The typical row of the character table consists mostly of character values, together with indicator and fusion information that is described in ATLAS. Usually the character values are ordinary integers, but certain algebraic irrationalities can also arise. In such cases we either print the ATLAS name for the desired irrationality in full, or just an algebraic conjugacy operator by which it can be obtained from a nearby entry in the same row. To be precise, this nearby entry can be any entry for a class in the same algebraically conjugate family as the desired one that is printed in full. In then next table we presents permutation characters of the second, fourth and sixth maximal subgroup of the group $J_{1}$.

Table 3.14:

| Maximal subgroups | $\chi_{M}$ |
| :---: | :---: |
| $2^{3}: 7: 3$ | $1 a+56 a b+76 a+77 b c+120 a b c+133 a+209 a$ |
| $2 \times A_{5}$ | $1 a+56 a b+76 a^{2}+77 a^{2}+120 a b c+133 a^{2}+209 a^{2}$ |
| $19: 6$ | $1 a+56 a b+76 a^{2}+77 a b c+120 a b c+133 a^{2}+209 a^{2}$ |
| $D_{6} \times D_{10}$ | $1 a+56 a b+76 a^{3}+77 a^{3}+120 a^{2} b^{2} c^{2}+133 a^{4} b c+209 a^{4}$ |

By Lemma 2.5.21 the group $J_{1}$ possesses no primitive genus zero, one and two system in its action on the right cosets of maximal subgroup 19: 6 and $D_{6} \times D_{10}$ because $1_{2^{3}: 7: 3}^{G}$ is submodule of $1_{19: 6}^{G}$ and $1_{2 \times A_{5}}^{G}$ is submodule of $1_{D_{6} \times D_{10}}^{G}$. Next Riemann Hurwitz formula implies that $J_{1}$ has one ramification type $(2 A, 3 A, 7 A)$ of genus zero in its action on the right cosets $L_{2}(11)$.

### 3.3.2 The Janko group $J_{2}$ and its Automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=J_{2}$. The Janko group $J_{2}$ has nine classes of maximal subgroups which are given in the first row in the Table 3.15. Note that the maximal fixed point ratio of the maximal subgroup $A_{5}$ is equal to $\frac{60}{10080}$. So Lemma 2.5 .19 implies that the group $J_{2}$ possesses no primitive genus zero, one and two system in its action on the right cosets of the maximal subgroup $A_{5}$. The indexes and number of ramification types of other classes of maximal subgroups are given in the rows two and three respectively.

Table 3.15:

| Maximal subgroups | $U_{3}$ | $3 . P G L_{2}(9)$ | $2^{1+4}: A_{5}$ | $2^{2+4}:\left(3 \times S_{3}\right)$ | $A_{4} \times A_{5}$ | $A_{5} \times D_{10}$ | $\left(L_{( }(3)(2): 2\right.$ | $5^{2}: D_{12}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 100 | 280 | 315 | 525 | 840 | 1008 | 1800 | 2016 |
| N.R.T | 58 | 19 | 14 | 1 | 1 | 2 | 1 | 2 |

A GAP calculation shows that the group algebra structure constant of 26 ramification types of first maximal subgroup, eight ramification types of second maximal subgroup and six ramification types of third maximal subgroup of above table are equal to zero and thus are ruled out. By using the Zariski condition we can eliminate two of the 58 ramification types of $J_{2}$ acting on the cosets of $U(3)$. Let $x, y$ and $z$ be representative of conjugacy classes $2 A, 4 A$ and 15 (AorB) respectively then there are conjugacy classes of pair $(x, y)$ such that whose product is equal to $z$. However the order group $\langle x, y\rangle$ is not equal to order of the group $J_{2}$. Hence $G$ is not of type $(2 A, 4 A, 15 A B)$. Using similar argument we can eliminate a further 23 ramification types of the first maximal subgroup, 10 ramification types of the second maximal and 7 ramification types of the third maximal subgroup. In the light of Lemma 2.5.21 all ramification types of the fourth class of maximal subgroup up to eighth class of maximal subgroups can be ruled out. By the next table we show the number of ramification types of maximal subgroups of Janko group $J_{2}$ which survive the filters.

Table 3.16:

| Maximal subgroups | $U_{3}$ | $3 . P G L_{2}(9)$ | $2^{1+4}: A_{5}$ | $2^{2+4}:\left(3 \times S_{3}\right)$ | $A_{4} \times A_{5}$ | $A_{5} \times D_{10}$ | $(L(3)(2): 2$ | $5^{2}: D_{12}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 100 | 280 | 315 | 525 | 840 | 1008 | 1800 | 2016 |
| N.R.T | 7 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |

Now we will use similar considerations for the automorphism group of $J_{2}$. Let $G$ be almost simple group $\operatorname{Aut}\left(J_{2}\right)$. The classes of maximal subgroup of $G$, their indexes, and number of ramification types of maximal subgroups are presented in the following table.

Table 3.17:

| Maximal subgroups | $U_{3}: 2$ | $3 . A_{6} \cdot 2^{2}$ | $2^{1+4}: S_{5}$ | $H .2$ | $\left(A_{4} \times A_{5}\right): 2$ | $\left(A_{5} \times D_{10}\right) \cdot 2$ | $(L 3)(2): 2 \times 2$ | $5^{2}:\left(4 \times S_{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 100 | 280 | 315 | 525 | 840 | 1008 | 1800 | 2016 |
| N.R.T | 82 | 17 | 15 | 2 | 26 | 10 | 1 | 4 |

By using the Zariski condition, the Generating Group Criterion, the ClassStructureCharacterTable function, and Lemma 2.5.21 all but 13 ramification types in the first maximal subgroup in the above table are eliminated.

### 3.3.3 The Janko group $J_{3}$ and its Automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=J_{3}$. The Janko group $J_{3}$ has eight classes of maximal subgroups which are given in the first row in the Table 3.18. The maximal fixed point ratios in the respective actions are given in row 3. The indexes of the maximal subgroups are given in row 2.

Table 3.18:

| Maximal subgroups | $L_{2}(16): 2$ | $L_{2}(19)$ | $2^{4}:\left(3 \times A_{5}\right)$ | $L_{2}(17)$ | $\left(3 \times A_{6}\right): 2_{2}$ | $3^{2} \cdot\left(3 \times 3^{2}\right): 8$ | $2^{1+4}: A_{5}$ | $2^{2+4}:\left(3 \times S_{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 6156 | 14688 | 17442 | 20520 | 23256 | 25840 | 26163 | 43605 |
| b | $\frac{76}{6156}$ | $\frac{96}{14688}$ | $\frac{72}{17442}$ | $\frac{120}{20520}$ | $\frac{136}{23256}$ | $\frac{80}{25840}$ | $\frac{131}{26163}$ | $\frac{90}{43605}$ |

Lemma 2.5.19 implies that no genus system $\overline{\mathrm{x}}=\left(x_{1}, x_{2}, \ldots, x_{r}\right)$ satisfies the Riemann Hurwitz formula if $b+\frac{1}{[G: M]}<\frac{1}{85}$. Thus the maximal subgroup $M=L_{2}(16): 2$ gives the only possible primitive action of $G$ which may possess a low genus system.

Table 3.19:

| Conjugacy class representative | 2 A | 3 A | 3 B | 4 A | 5 A | 5 B | 6 A | 8 A | 9 A | 9 B | 9 C |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| indexes | 3040 | 4080 | 4104 | 4592 | 4924 | 4924 | 5104 | 5374 | 5472 | 5472 | 5472 |
| Conjugacy class representative | 10 A | 10 B | 12 A | 15 A | 15 B | 17 A | 17 B | 19 A | 19 B |  |  |
| indexes | 5532 | 5532 | 5628 | 5740 | 5740 | 5792 | 5792 | 5832 | 5832 |  |  |

According to the above Table 3.19, the Riemann Hurwitz formula implies that $G$ has one ramification type $(3 B, 3 B, 3 B)$ of genus one system, which is eliminated by the Zariski condition. Hence the group $G$ possesses no primitive genus zero, one and two systems in its action on the right cosets of all maximal subgroups.

Let $G$ be the almost simple group $\operatorname{Aut}\left(J_{3}\right)$. The group $G$ has seven class of maximal subgroups which are given in the table. Similarly, the maximal fixed point ratio in the respective actions are given in row 3 and the indexes of maximal subgroups are given in row 2 .

Table 3.20:

| Maximal subgroups | $L_{2}(16): 4$ | $2^{4}:\left(3 \times A_{5}\right) \cdot 2$ | $L_{2}(17)$ | $\left(3 \times M_{10}\right): 2$ | $3^{2} .\left(3 \times 3^{2}\right): 8.2$ | $2^{1+4}: S_{5}$ | $2^{2+4}:\left(S_{3} \times S_{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 6156 | 17442 | 20520 | 23256 | 25840 | 26163 | 43605 |
| b | $\frac{76}{6156}$ | $\frac{102}{17442}$ | $\frac{154}{20520}$ | $\frac{136}{23256}$ | $\frac{80}{25840}$ | $\frac{153}{26163}$ | $\frac{255}{43605}$ |

Lemma 2.5.19 implies that the maximal subgroup $L_{2}(16): 4$ is the only possible primitive action of $G$ which may possess a low genus system.

Table 3.21: Index on maximal subgroup $L_{2}(16): 4$

| Conjugacy class representative | 2A | 2B | 3 A | 3B | 4 A | 4 B | 5 A | 6 A | 6 B | 8 A | 8 B | 9 A | 9 B |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| indexes | 3040 | 3078 | 4080 | 4104 | 4592 | 4594 | 4924 | 5104 | 5130 | 5374 | 5374 | 5472 | 5472 |
| Conjugacy class representative | 10 A | 12 A | 12 B | 15 A | 17 A | 17 B | 18 A | 18 B | 18 C | 19 A | 24 A | 24 B | 34 A |
| indexes | 5532 | 5628 | 5628 | 5740 | 5792 | 5792 | 5814 | 5814 | 5814 | 5832 | 5892 | 5892 | 5974 |
| Cor | 5974 |  |  |  |  |  |  |  |  |  |  |  |  |

According to the above table, Riemann Hurwitz formula implies that $G$ has three ramification types $(3 B, 3 B, 3 B),(2 B, 2 B, 2 B, 2 B),(2 B, 3 B, 6 B)$ of genus one system which are eliminated by the Zariski condition. Hence the group $G$ possesses no primitive genus zero one and two systems in its action on the right cosets of any maximal subgroups.

### 3.3.4 The Janko group $J_{4}$

The largest Janko group $J_{4}$ has order 86775571046077562880 . The classes of maximal subgroups of $J_{4}$, their indexes and their maximal fixed point ratios in their representative actions are given in the following table.

Table 3.22:

| M.S | $2^{11}: M_{24}$ | $2^{10}: L_{5}(2)$ | $2^{1+12}: 3 . M_{22} .2$ | $2^{3+12} .\left(S_{5} \times L_{3}(2)\right)$ | $U_{3}(11): 2$ | $11^{1+2}:\left(5 \times 2 S_{4}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Ind | 173067389 | 8474719242 | 3980549947 | 131358148251 | 611822174208 | 2716499045348352 |
| b | $\frac{53349}{17367389}$ | $\frac{285450}{8474719242}$ | $\frac{194107}{3980549947}$ | $\frac{1421211}{131358148251}$ | $\frac{2064384}{611822174208}$ | $\frac{8257536}{2716499045348352}$ |
| M.S | $L_{2}(23)$ : 5 | $L_{2}(23): 2$ | 29:28 | 43 : 14 | 37: 12 |  |
| Ind | 530153782050816 | 7145550975467520 | 106866466805514240 | 144145466853949440 | 195440475329003520 |  |
| b | $\frac{11354112}{530153782050816}$ | $\frac{454164480}{7145550975467520}$ | $\frac{64880640}{106866466805514240}$ | $\frac{129761280}{144145466853949440}$ | $\frac{151388160,}{195440475329003520}$ |  |

Lemma 2.5.19 implies that the group $G$ possesses no primitive genus zero one and two systems in its action on the right cosets of any maximal subgroup.

### 3.4 The ramification types of the Conway groups

In this section we are going to determine all possible ramification types for the Conway groups. Firstly we start by determining the ramification types of the smallest Conway group $\mathrm{Co}_{3}$.

### 3.4.1 The Conway group $\mathrm{Co}_{3}$

Let $G$ be a Conway group $\mathrm{Co}_{3}$. The group $G$ has 14 conjugacy classes of maximal subgroups which are presented in the first row of the table 3.23. The indexes and the maximal fixed point ratios in the representative actions are given in the second and third rows of the table 3.23 respectively.

Lemma 2.5.19 implies that if $M$ be any maximal subgroup for the group $C o_{3}$ and $b+\frac{1}{[G: M]}<\frac{1}{85}$, then $G$ possesses no primitive genus system in its action on the right cosets of the maximal

Table 3.23:

| Max.Subgroups | $M c L: 2$ | $H S$ | $U_{4}(3):\left(2^{2}\right)_{133}$ | $M_{23}$ | $3^{5}:\left(2 \times M_{11}\right)$ | $2 . S_{6}(2)$ | $U_{3}(5): S_{3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

subgroup $M$. Thus the maximal subgroups $M c L_{2}, H S, U_{4}(3):\left(2^{2}\right)_{133}$ and $M_{23}$ are the only possible primitive actions of $G$ which may possibly posses a low genus system.

According to the Riemann Hurwitz formula $\mathrm{Co}_{3}$ has 50 possible ramification types of genus zero, one and two systems in its action on the right coset of the maximal subgroups McL:2 , $H S, M_{23}$ and $U_{4}(3):\left(2^{2}\right)_{133}$. Given an element $z$ of order eleven of type A or B, there are conjugacy classes of pairs $(x, y)$ of order two of type A and three of type A respectively such that $x y=z^{-1}$. However, order of the groups which are generated by conjugacy classes of the pairs $(x, y)$ are not equal to the order of the group Co3. It follows that the triple $(2 A, 3 A, 11 A B)$ can be eliminated. Similarly, by the same argument 38 ramification types can be eliminated. Moreover, 7 of ramification types can be eliminated by the Zariski condition. Finally a GAP calculation shows that the group algebra structure constant of three of the ramification types is equal to zero, so these are also eliminated. Thus all 50 ramification types of $\mathrm{Co3}$ can be eliminated except $(2 B, 3 C, 7 A)$ of genus zero in its action of the right coset of the maximal subgroups McL: 2.

### 3.4.2 The Conway group $\mathrm{Co}_{2}$ and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=\mathrm{Co}_{2}$. The group $\mathrm{Co}_{2}$ has eleven conjugacy classes of maximal subgroups which are given in the first row in the Table 3.24. Note that the maximal fixed point ratio of $G$ actions on the maximal subgroup $2^{4+10}\left(S_{5} \times S_{3}\right), M_{23}, 3^{1+4}$ : $2^{1+4} . s_{5}$ and $5^{1+2}: 4 S_{4}$ are equal to $\frac{34083}{3586275}, \frac{15360}{4147200}, \frac{71680}{45337600}, \frac{86016}{3525417662}$ respectively. So Lemma 2.5.19 implies that the group $\mathrm{Co}_{2}$ possesses no primitive genus zero, one and two system in its action on the right cosets of these maximal subgroups. The indexes and number of ramification types of the other class of maximal subgroups are given in the rows two and three respectively.

A GAP calculation shows that the group algebra structure constant of four ramification types of

Table 3.24:

| Maximal subgroups | $U_{6}(2): 2$ | $2^{10}: M_{22}: 2$ | $M c L$ | $2^{1+8}: S_{6}(2)$ | $H S: 2$ | $\left(2^{1+6} \times 2^{4}\right) \cdot A_{8}$ | $U_{4}(3) \cdot D_{8}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes in G | 2300 | 46575 | 47104 | 46925 | 476928 | 1024650 | 1619200 |
| N.R.T | 13 | 1 | 0 | 1 | 0 | 0 | 0 |

the first maximal subgroup are equal to zero, so these will be ruled out. By using the Zariski condition 4 ramification types of the first maximal subgroup, one ramification types of the second maximal subgroup and one ramification of the fourth maximal subgroup are eliminated.

Finally five ramification types in the first maximal subgroup can be eliminated by using Generating Group Criterion. Hence $G$ possesses no primitive genus zero, one and two systems.

If $G=A u t\left(\mathrm{Co}_{2}\right)=\operatorname{Co} 2: 2$, then $G$ possesses no primitive genus zero, one and two system because all ramification types ruled out by arguments the similar to the ones given above.

### 3.4.3 The Conway group $\mathrm{Co}_{1}$

Let $G$ be a group Co1. The conjugacy classes of maximal subgroups of $G$,their indexes and their maximal fixed point ratios in their representative actions are given in the following table.

Table 3.25:

| Maximal subgroups | Indexes | fixed point ratio |
| :---: | :---: | :---: |
| $\mathrm{Co}_{2}$ | 98280 | $\frac{2280}{98280}$ |
| 3.Suz:2 | 1545600 | $\frac{22881}{1545600}$ |
| $2^{11}: M_{24}$ | 8282375 | $\frac{32535}{8282375}$ |
| $\mathrm{Co}_{3}$ | 8386560 | $\frac{38720}{8386560}$ |
| $2^{1+8} . O_{8}(2)$ | 46621575 | $\frac{135135}{46621575}$ |
| $U_{6}(2): S_{3}$ | 75348000 | $\frac{132640}{75348000}$ |
| $\left(A_{4} \times G_{2}(4)\right): 2$ | 688564800 | $\frac{928422}{68854800}$ |
| $2^{2+12}:\left(A_{8} \times S_{3}\right)$ | 2097970875 | $\frac{1216215,}{2097970875}$ |
| $2^{4+12} .\left(S_{3} \times 3 S_{6}\right)$ | 4895265375 | $\frac{1143135}{4895265375}$ |
| $3^{2} . U_{4}(3) . D_{8}$ | 17681664000 | $\frac{3226080}{17681664000}$ |
| $3^{6}: 2 M_{12}$ | 30005248000 | $\frac{2867200}{30005248000}$ |
| $\left(A_{5} \times J_{2}\right): 2$ | 57288591360 | $\frac{10149024}{57288591360}$ |
| $3^{1+4}: 20_{4}(2): 2$ | 165028864000 | $\frac{52831800}{\frac{128500}{165028864000}}$ |
| $\left(A_{6} \times U_{3}(3)\right): 2$ | 954809856000 | $\frac{2956524880}{9548085000}$ |
| $3^{3+4}: 2\left(S_{4} \times S_{4}\right)$ | 1650288640000 | $\frac{954809850000}{\frac{4164600}{1650288640000}}$ |
| $A_{9} \times S_{3}$ | 3819239424000 | $\frac{1627564360}{3819239424000}$ |
| $\left(A_{7} \times L_{2}(7)\right): 2$ | 4910450688000 | $\frac{1111966800}{4910450688000}$ |
| $\left(D_{10} \times\left(A_{5} \times A_{5}\right) \cdot 2\right) .2$ | 28873450045440 | $\frac{373621248}{28873450045440}$ |
| $5^{1+2}: G L_{2}(5)$ | 69296280109056 | $\frac{111476756}{69296280100056}$ |
| $7^{2}:\left(3 \times 2 A_{4}\right)$ | 1178508165120000 | $\frac{546720}{\frac{5950}{1178508165120000}}$ |

Lemma 2.5.19 implies that the maximal subgroups $\mathrm{Co}_{2}$ and $3 . S u z: 2$ are the only possess primitive action of $G$ which may possess a low genus system.

Riemann Hurwitz formula implies that G has 6 possible ramification types of genus zero and one systems. All of them can be ruled out using the Zariski condition, the Generating Group

### 3.5 The ramification types of the Higman-Sims group and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=H S$. The group $H S$ has ten conjugacy classes of maximal subgroups which are given in the first row in the table 3.26. we note that the maximal fixed point ratios of the classes of maximal subgroups $2 \times A_{6} .2^{2}$ and 5:4× $A_{5}$ are equal to $\frac{2}{154}$ and $\frac{216}{36960}$ respectively. So Lemma 2.5 .19 implies that the group $G$ possesses no primitive genus zero, one and two system in its action on the right cosets of the maximal subgroup $2 \times A_{6} .2^{2}$ and 5:4× $A_{5}$. The indexes and number of ramification types of the maximal subgroups are given in the rows two and three respectively.

Table 3.26:

| Maximal subgroups | $M_{22}$ | $U_{3}(5): 2$ | $L_{3}(4): 2_{1}$ | $S_{8}$ | $2^{4} \cdot S_{6}$ | $4^{3}: L_{3}(2)$ | $M_{11}$ | $4.2^{4}: S_{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 100 | 176 | 1100 | 1100 | 3850 | 4125 | 5600 | 5775 |
| N.R.T | 78 | 28 | 3 | 6 | 0 | 0 | 0 | 0 |

GAP calculation shows that the group algebra structure constant of 18 of ramification types of first maximal subgroup and 9 ramification types of the second maximal subgroup are equal to zero, so they can be eliminated. Furthermore, 5 ramification types of the first maximal subgroup and 2 ramification types of the second maximal subgroup will be eliminated by the Zariski condition. Given an element $z$ of order ten of type A, there are conjugacy classes of pairs $(x, y)$ of order two of type B and three of type A such that $x y=z^{-1}$. However, order of the groups which are generated by conjugacy classes of the pairs $(x, y)$ are not equal to the order of the group $H S$. It follows that the triple $(2 B, 3 A, 10 A)$ of genus zero system can be eliminated. By a similar argument 42 of the ramification types of the first maximal subgroup and 17 ramification types of the second maximal subgroup can be eliminated. Note that the permutation character of the maximal subgroup $U_{3}(5): 2$ lies in the permutation character of the maximal subgroups $L_{3}(4): 2_{1}$ and $S_{8}$. So $1_{U_{3}(5): 2}^{G}$ is a submodule of $1_{L_{3}(4): 2_{1}}^{G}$ and $1_{S_{8}}^{G}$. By using Lemma 2.5.21 we can eliminate three ramification types the third maximal subgroup and 6 ramification types of the fourth maximal subgroup. Hence we have to find braid orbits of 9 tuples of the group $H S$. All of these are in the action of $G$ on the first maximal subgroup.

Let $G$ be a group $\operatorname{Aut}(H S)$, then $G$ has eight classes of maximal subgroups. The maximal fixed point ratio of the maximal subgroups $H .2$ and $5: 4 \times S_{5}$ are equal to $\frac{2}{154}, \frac{216}{36960}$ respectively. So Lemma 2.5.19 implies that the group $G$ possesses no primitive genus zero, one and two system in its action on the right cosets of the maximal subgroup $2 \times A_{6} .2^{2}$ and $5: 4 \times A_{5}$. The other maximal subgroups are given in the first row of the table 3.27. The indexes and number of ramification types of the maximal subgroups are given in the rows two and three respectively.

Table 3.27:

| Maximal subgroups | $M_{22}: 2$ | $L_{3}(4): 2^{2}$ | $S_{8} \times 2$ | $2^{5} \cdot S_{6}$ | $4^{3}:\left(L_{3}(2) \times 2\right)$ | $2^{1+6}: S_{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 100 | 1100 | 1100 | 3850 | 4125 | 5775 |
| N.R.T | 78 | 3 | 6 | 0 | 0 | 0 |

By using the Zariski condition and the Generating Group Criterion all but 29 of ramification types in the first maximal subgroup in the Table 3.27 are eliminated.

### 3.6 The ramification types of the Fischer Groups

The Fischer groups are $F i_{22}, F_{23}$ and $F i_{24}$. In this section we discuss why the Fischer groups do not possess primitive genus zero, one and two systems.

### 3.6.1 The Fischer group $F i_{22}$ and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=F i_{22}$. The group $G$ has 12 conjugacy classes of maximal subgroups. Note that the maximal fixed point ratios of the maximal subgroups $3^{1+6}: 2^{3+4}: 3^{2}: 2, S_{10}$ and $M_{12}: 2$ are equal to $\frac{9856}{12812800}, \frac{228096}{17791488}$ and $\frac{221184}{679311360}$ respectively. So Lemma 2.5.19 implies that the group $G$ possesses no primitive low genus systems in its action on the right cosets of the maximal subgroups $3^{1+6}: 2^{3+4}: 3^{2}: 2, S_{10}$ and $M_{12}: 2$. All other maximal subgroups and their indexes and possible number of ramification types are given in the following table.

Table 3.28:

| Maximal subgroups | $2 . U_{6}(2)$ | $O_{7}(3)$ | $O_{8}(2): S_{3}$ | $2^{10}: M_{22}$ | $2^{6}: S_{6}(2)$ | $\left(2 \times 2^{1+8}: U_{4}(2)\right): 2$ | $2_{F_{4}(2)}$ | $2^{5+8}:\left(S_{3} \times S_{6}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 3510 | 14080 | 61776 | 142155 | 694980 | 1216215 | 1647360 | 3592512 |
| N.R.T | 11 | 1 | 0 | 10 | 0 | 0 | 0 | 0 |

A GAP calculation shows that the group algebra structure constant of 3 ramification types of the first maximal subgroup is equal to zero, so these can be eliminated. By using the Zariski
condition two ramification types of the first maximal subgroup, one ramification type of the second maximal subgroup and 10 ramification types of the fourth maximal subgroup can be ruled out. Finally, given an element $z$ of order eight of type A, there are conjugacy classes of pairs $(x, y)$ of order two of type B and three of type A such that $x y=z^{-1}$. However, orders of the groups which are generated by conjugacy classes of the pairs $(x, y)$ are not equal to the order of the group $G$. It follows that the triple $(2 B, 3 A, 8 A)$ can be eliminated. Using similar considerations we eliminate a further 6 ramification types of the first maximal subgroup. Hence $G$ possesses no primitive low genus systems.

Similarly, if $G$ is the group $F i_{22}: 2$ then $G$ has no primitive low genus system in its action on any maximal subgroup.

### 3.6.2 The Fischer group $F i_{23}$

Let $G$ be a Fischer group $F i_{23}$. The group $F i_{23}$ has 14 conjugacy classes of maximal subgroups which are given in the first column in the Table 3.29. The maximal fixed point ratios in the respective actions are given in column 3. The indexes of maximal subgroups are given in column 2.

Table 3.29:

| MaximalSubgroups | Indexes | Maximal fixed pointratio |
| :---: | :---: | :---: |
| $2 . F i_{22}$ | 31671 | $\frac{3511}{31671}$ |
| $O_{8}{ }^{+}(3): S_{3}$ | 137632 | $\frac{14080}{137632}$ |
| $2^{2} \cdot U_{6}(2) .2$ | 55582605 | $\frac{1219725}{55582605}$ |
| $S_{8}(2)$ | 86316516 | $\frac{694980}{86316516}$ |
| $S_{3} \times O_{7}(3)$ | 148642560 | $\frac{1661440}{148642560}$ |
| $2^{11} \cdot M_{23}$ | 195747435 | $\frac{142155}{195747435}$ |
| $3_{+}{ }^{1+8} .2^{1+6} \cdot 3^{1+2} \cdot 2 S$ | 1252451200 | $\frac{12812800}{1252451200}$ |
| $3^{3} \cdot\left[3^{7}\right] \cdot\left(2 \times L_{3}(3)\right)$ | 6165913600 | $\frac{15769600}{6165913600}$ |
| $S_{12}$ | 8537488128 | $\frac{17791488}{8537488128}$ |
| $\left(2^{2} \times 2^{1+8}\right) \cdot\left(3 \times U_{4}(2)\right) .2$ | 12839581755 | $\frac{74189115}{12839581755}$ |
| $2^{6+8}:\left(A_{7} \times S_{3}\right)$ | 16508033685 | $\frac{28667925}{16508033685}$ |
| $S_{4} \times S_{6}(2)$ | 117390461760 | $\frac{255752640}{117390461760}$ |
| $S_{4}(4): 4$ | 1044084577536 | $\frac{35126784}{1044084577536}$ |
| $L_{2}(17): 2$ | 673496454758400 | $\frac{13271040}{673496454758400}$ |

Lemma 2.5.19 implies that the maximal subgroups 2.Fi $i_{22}, O_{8}{ }^{+}(3): S_{3}$ and $2^{2} . U_{6}(2) .2$ are the only possible primitive actions of $G$ which may possesses a low genus system.

Riemann Hurwitz formula implies that G has no possible ramification types of genus zero, one and two systems, in its action on the right cosets of 2.Fi22, $O_{8}{ }^{+}(3): S_{3}$ and $2^{2} . U_{6}(2) .2$. Hence $G$ poss no primitive low genus system.

### 3.6.3 Fischer group $F i_{24}$ and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=F i_{24}$. The group $G$ has 20 classes of maximal subgroups which are given in the first column in the table 3.30. The maximal fixed point ratios in the respective actions are given in column 3. The index of maximal subgroups are given in column 2.

We observe the upper bound fixed point ratio is approximately $\leqslant \frac{1}{90}$. Thus Lemma 2.5.19 implies that the group $G$ possesses no primitive genus zero, one and two systems in its action on it's maximal subgroups. Similarly, if $G$ is almost simple group $F i_{24}: 2$ then the upper bound for the fixed point ratios is $\leqslant \frac{1}{90}$. Hence $F i_{24}: 2$ possesses no primitive low genus system in its action for the right cosets of its 18 conjugacy classs of maximal subgroups.

Table 3.30:

| MaximalSubgroups | Indexes | Maximal fixedpointratio |
| :---: | :---: | :---: |
| $F i_{23}$ | 306936 | $\frac{3512}{306936}$ |
| 2.Fi $i_{22}: 2$ | 4860485028 | $\frac{1346788}{4860485028}$ |
| $\left(3 \times O_{8}(3): 3\right): 2$ | 14081405184 | $\frac{1675520}{14081405184}$ |
| $O_{10}(2)$ | 50177360142 | $\frac{7992270}{50177360142}$ |
| $3^{7} . O(3)$ | 125168046080 | $\frac{5125120}{125168046080}$ |

| $A_{6} \times L_{2}(8): 3$ | 574727888823563059200 | $\frac{12421693440}{574727888823563059200}$ |

### 3.7 The ramification types of the $M^{c}$ Laughlin group and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=M^{c} L$. The group $G$ has 10 conjugacy classes of maximal subgroups. Based on the fact, that the maximal fixed point ratio on the classes of maximal subgroups $3^{1+4}: 2 S_{5}, 2 . A_{8}, M_{11}$, and $5^{1+2}: 3: 8$ is equal to $\frac{91}{15400}, \frac{211}{22275}, \frac{84}{11340}$, and $\frac{486}{299376}$ respectively, Lemma 2.5.19 guarantees that the group $G$ possesses no primitive low genus systems in its action on the right cosets of those classes of maximal subgroups. Moreover, the six remaining classes of maximal subgroups, their indexes, and number of ramification types are given in the following table.

Table 3.31:

| Maximal subgroups | $U_{4}(3)$ | $M_{22}$ | $U_{3}(5)$ | $3^{4}: M_{10}$ | $L_{3}(4): 2_{2}$ | $2^{4}: A_{7}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Indexes | 275 | 2025 | 7128 | 15400 | 22275 | 22275 |
| N.R.T | 11 | 2 | 1 | 0 | 1 | 1 |

Note that the group algebra structure constant of seven ramification types of the first maximal subgroup in the Table 3.31 are equal to zero, so they can be ruled out. Furthermore, two ramification types of the first maximal subgroup, one ramification type of the second, third, fourth and fifth maximal subgroups can be eliminated by using the Zariski condition. Finally, by using the Generating Group Criterion 2 of ramification types of the first maximal subgroup and one ramification type of the second maximal subgroup can not occur. Hence $G$ possesses no primitive low genus system.

Now, let $G=\operatorname{Aut}\left(M^{c} L\right)=M^{c} L: 2$, then $G$ has eight classes of maximal subgroups. The maximal fixed point ratio on the maximal subgroups $3^{1+4}: 4 S_{5}, 2 . s_{8}, M_{11} \times 2$ and $H .2$ is equal to $\frac{110}{15400}, \frac{211}{22275}, \frac{84}{11340}$ and $\frac{486}{299376}$ respectively. So Lemma 2.5 .19 implies that the group $G$ possesses no primitive low genus system in its action of those maximal subgroups. The other maximal subgroups, their indexes, and number of ramification types are given in the following table.

Now we will make an analysis of $M^{c} L: 2$ similar to that given above. By using the Generating Group Criterion and the Zariski condition all ramification types of the table above are eliminated. Hence $G$ possesses no primitive genus zero, one and two system.

Table 3.32:

| Maximal subgroups | $U_{4}(3): 2_{3}$ | $U_{3}(5): 2$ | $3^{4}:\left(M_{10} \times 2\right)$ | $L_{3}(4): 2^{2}$ |
| :---: | :---: | :---: | :---: | :---: |
| Indexes | 275 | 7128 | 15400 | 22275 |
| N.R.T | 22 | 5 | 0 | 1 |

### 3.8 Ramification types of the Suzuki group and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=S u z$. The group $G=\operatorname{Suz}$ has 16 conjugacy classes of maximal subgroups which are given in the first column in the table 3.33. The indexes of maximal subgroups and the maximal fixed point ratios in the respective actions are given in the columns two and three respectively.

Table 3.33:

| MaximalSubgroups | Indexes | Maximal fixedpointratio |
| :---: | :---: | :---: |
| $G_{2}(4)$ | 1782 | $\frac{162}{1782}$ |
| $3_{2} \cdot U_{4}(3): 2_{3}$ | 22880 | $\frac{480}{22880}$ |
| $U_{5}(2)$ | 32760 | $\frac{760}{32760}$ |
| $2^{1+6} . U_{4}(3)$ | 135135 | $\frac{2835}{135135}$ |
| $3^{5}: M_{11}$ | 232960 | $\frac{2560}{232960}$ |
| $J_{2}: 2$ | 370656 | $\frac{4536}{370656}$ |
| $2^{4+6}: 3 A_{6}$ | 405405 | $\frac{2205}{405405}$ |
| $\left(A_{4} \times L_{3}(4)\right): 2_{1}$ | 926640 | $\frac{2160}{926640}$ |
| $2^{2+8}:\left(A_{5} \times S_{3}\right)$ | 1216215 | $\frac{8505}{1216215}$ |
| $M_{12}: 2$ | 2358720 | $\frac{8640}{2358720}$ |
| $3^{2+4}: 2\left(A_{4} \times 2^{2}\right) \cdot 2$ | 3203200 | $\frac{5320}{3203200}$ |
| $\left(A_{6} \times A_{5}\right): 2$ | 10378368 | $\frac{4536}{10378368}$ |
| $\left(3^{2}: 4 \times A_{6}\right) .2$ | 17297280 | $\frac{15120}{17297280}$ |
| $L_{3}(3): 2$ | 39916800 | $\frac{34560}{39916800}$ |
| $L_{2}(25)$ | 57480192 | $\frac{6780}{5740192}$ |
| $A_{7}$ | 17714880 | $\frac{6720}{17714880}$ |

Clearly, the maximal subgroups $G_{2}(4), 3_{2} \cdot U_{4}(3): 2_{3}, U_{5}(2), 2^{1+6} \cdot U_{4}(3), 3^{5}: M_{11}$ are the only subgroups where a primitive action of low genus is possible (Lemma 2.5.19). So we present the number of ramification types of those maximal subgroups in the following table

Table 3.34:

| Maximal subgroups | $G_{2}(4)$ | $3_{2} . U_{4}(3): 2_{3}$ | $U_{5}(2)$ | $2^{1+6} . U_{4}(3)$ | $3^{5}: M_{11}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| N.R.T | 4 | 0 | 4 | 1 | 2 |

Note that the group algebra structure constant of three ramification types of the first maximal subgroup is equal to zero, so they can not occur. By using the Zariski condition one ramification type of the first maximal subgroup and four ramification types of the third maximal subgroup, one ramification type of the fourth and two ramification types of the fifth maximal subgroup will be ruled out. Hence $G$ possesses no primitive genus low genus system in its action on the maximal subgroups.

Let $G=\operatorname{Aut}(S u z)=\operatorname{Suz}: 2 . G$ has 15 classes of maximal subgroups which are given in the first column of Table 3.35. The indexes of the maximal subgroups are given in the second column and the maximal fixed point ratios are given in the third column.

According to the maximal fixed point ratio, the maximal subgroups $G_{2}(4): 2,3 U_{4}(3) \cdot\left(2^{2}\right)_{133}$, $U_{5}(2): 2,2^{1+6} \cdot U_{4}(3) \cdot 2,3^{5}:\left(M_{11} \times 2\right)$ are the only ones in which $G$ may allows a primitive action of low genus (Lemma 2.5.19). The Riemann Hurwitz formula allows 20 possible ramification types. All of them can be eliminated by using the Zariski condition and the Group Generating Criterion.

### 3.9 The ramification types of the Held group and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=H e$. The group $G=H e$ has 10 conjugacy classes of maximal subgroups which are given in the first column in the Table 3.36. The indexes of maximal subgroups and the maximal fixed point ratios in the respective actions are given in the columns two and three respectively.

The only possible primitive actions where $G$ may have a possible low genus systems are on the

Table 3.35:

| MaximalSubgroups | Indexes | Maximal fixedpointratio |
| :---: | :---: | :---: |
| $G_{2}(4): 2$ | 1782 | $\frac{162}{1782}$ |
| $3 U_{4}(3) \cdot\left(2^{2}\right)_{133}$ | 22880 | $\frac{480}{22880}$ |
| $U_{5}(2): 2$ | 32760 | $\frac{760}{32760}$ |
| $2^{1+6} . U_{4}(3) .2$ | 135135 | $\frac{2835}{135135}$ |
| $3^{5}:\left(M_{11} \times 2\right)$ | 232960 | $\frac{2560}{232960}$ |
| $J_{2}: 2 \times 2$ | 370656 | $\frac{4536}{37056}$ |
| $2^{4+6}: 3 S_{6}$ | 405405 | $\frac{2205}{405405}$ |
| $\left(A_{4} \times L_{3}(4): 2_{3}\right): 2$ | 926640 | $\frac{2460}{926540}$ |
| $2^{2+8}:\left(S_{5} \times S_{3}\right)$ | 1216215 | $\frac{8505}{1216215}$ |
| $M_{12}: 2 \times 2$ | 2358720 | $\frac{8460}{2358720}$ |
| $3^{2+4}: 2\left(S_{4} \times D_{8}\right)$ | 3203200 | $\frac{5320}{3203200}$ |
| $\left(A_{6}: 2_{2} \times A_{5}\right): 2$ | 10378368 | $\frac{9408}{10378368}$ |
| $\left(3^{2}: 8 \times A_{6}\right) .2$ | 17297280 | $\frac{15152}{17297280}$ |
| $L_{2}(25): 2$ | 57480192 | $\frac{10080}{57400192}$ |
| $S_{7}$ | 17714880 | $\frac{6720}{17714880}$ |

classes of maximal subgroups $S_{4}(4): 2,2^{2} . L_{3}(4) . S_{3}$, and $2^{6}: 3 . S_{6}$. The first maximal subgroup has 8 ramification types such that all of them can be ruled out by the Generating Group Criterion. The second and third maximal subgroups have no ramification types. Hence $G$ possesses no primitive genus systems in its action in the right cosets of maximal subgroups.

Similarly, if $G=A u t(H e)=H e .2$, then the only possible primitive actions of $G$ for which a low genus systems may occur are on the classes of maximal subgroups $S_{4}(4): 4,2^{2} \cdot L_{3}(4) \cdot D_{12}$. The first maximal subgroup has eight ramification types and all of them can be ruled out. The second maximal subgroup has no possible ramification types of low genus system. Thus $G$ possesses no primitive genus system in its action on the right cosets of maximal subgroups.

Table 3.36:

| MaximalSubgroups | indexes | Maximal fixed point ratio |
| :---: | :---: | :---: |
| $S_{4}(4): 2$ | 2058 | $\frac{154}{2058}$ |
| $2^{2} \cdot L_{3}(4) \cdot S_{3}$ | 8330 | $\frac{346}{8330}$ |
| $2^{6}: 3 . S_{6}$ | 29155 | $\frac{651}{29155}$ |
| $2^{1+6} \cdot L_{3}(2)$ | 187425 | $\frac{945}{187425}$ |
| $7^{2}: 2 L_{2}(7)$ | 244800 | $\frac{84}{244800}$ |
| $3 . S_{7}$ | 266560 | $\frac{1792}{26560}$ |
| $7^{1+2}:\left(S_{3} \times 3\right)$ | 652800 | $\frac{120}{682800}$ |
| $S_{4} \times L_{3}(2)$ | 999600 | $\frac{2880}{999600}$ |
| $7: 3 \times L_{3}(2)$ | 1142400 | $\frac{960}{1142400}$ |
| $5^{2}: 4 A_{4}$ | 3358656 | $\frac{4032}{3358656}$ |

### 3.10 The ramification types of the Rudvalis group and its automorphism group

Let $G$ be an almost simple group such that $F^{*}(G)=R u$. The group $G=R u$ has 15 conjugacy classes of maximal subgroups which are given in the first column in the Table 3.37. The indexes of the maximal subgroups and the maximal fixed point ratios in the respective actions are given in the columns two and three respectively.

Lemma 2.5.19 implies that the maximal subgroup ${ }^{2} F_{4}(2)$ is the only possible primitive action of $G$ which may possesses a low genus system.

Riemann Hurwitz formula implies that G has no possible ramification types of genus zero, one or two systems in its action on the right cosets ${ }^{2} F_{4}(2)$. Hence, $G$ possesses no primitive genus system in its action on the right cosets of maximal subgroups.

If $G=\operatorname{Aut}(R u)=R u: 2$, then in similar way we can show that $G$ possesses no primitive low genus system in its action on the right cosets of maximal subgroups.

| MaximalSubgroups | Table 3.37: Ru |  |
| :---: | :---: | :---: |
| ${ }^{2} F_{4}(2)$ | 4060 | $\frac{92}{4060}$ |
| $\left(2^{6}: U_{3}(3)\right): 2$ | 188500 | $\frac{980}{188500}$ |
| $\left(2^{2} \times S z(8)\right): 3$ | 417600 | $\frac{456}{417600}$ |
| $2^{3+8}: L_{3}(2)$ | 424125 | $\frac{1085}{424125}$ |
| $U_{3}(5): 2$ | 579072 | $\frac{1536}{579072}$ |
| $2.2^{4+6}: S_{5}$ | 593775 | $\frac{1391}{593775}$ |
| $L_{2}(25) .2^{2}$ | 4677120 | $\frac{3584}{4677120}$ |
| $A_{8}$ | 7238400 | $\frac{3840}{7238400}$ |
| $L_{2}(29)$ | 11980800 | $\frac{4160}{11980800}$ |

| $5: 4 \times A_{5}$ | 121605120 | $\frac{8736}{121605120}$ |

### 3.11 The ramification types of the large sporadic simple groups

In this section we are going to prove that the large sporadic simple groups $H N, L y, O N, T h, B$ and $M$ possess no primitive genus systems in their actions on the right cosets of their maximal subgroups. Now we give tables such that the maximal subgroups are given in the first column, the indexes of the maximal subgroups, and the maximal fixed point ratios in the respective actions are given in columns two and three respectively

Table 3.38: HN

| MaximalSubgroups | indexes | Maximal fixed point ratio |
| :---: | :---: | :---: |
| $A_{12}$ | 1140000 | $\frac{8800}{1140000}$ |
| $2 . H S .2_{3}$ | 1539000 | $\frac{7979}{1539000}$ |
| $U_{3}(8): 3$ | 16500000 | $\frac{19200}{16500000}$ |
| $2^{1+8} .\left(A_{5} \times A_{5}\right) \cdot 2$ | 74064375 | $\frac{51975}{74064375}$ |
| $\left(D_{10} \times U_{3}(5)\right) \cdot 2$ | 108345600 | $\frac{37312}{108345600}$ |
| $5^{1+4}: 2^{1+4} \cdot 5 \cdot 4$ | 136515456 | $\frac{10368}{136515456}$ |

If $G \simeq H N, L y, O N, T h$, or $B$, then the fixed point ratios and indexes satisfy the hypothesis to Lemma 2.5.19. Thus these group do not possess primitive low genus systems.

The maximal subgroups of the Monster simple group have not been completely classified in the sense that the proof that the maximal 2-locals are exactly those given in the ATLAS exists only in the form of a preprint[29]. The other maximal subgroups were determined in [3].

Lemma 3.11.1. Let $G$ be a group. If for all irreducible complex characters $\chi_{i}(g), \chi_{i}(g) / \chi_{i}(1)<$ $\frac{1}{k+1}$ with $\chi_{i}(g) \neq \chi_{i}(1)$ then $\frac{f(g)}{k}<\frac{1}{k}, \forall g \in G$.

A complete proof can be found in [24]. This lemma guarantees us that all fixed point ratios of all nontrivial elements of their actions on the known maximal subgroup are $<\frac{1}{100}$ except that for element $2 A$ which is $<\frac{1}{44}$. So by Table 2 in [24] the only possible ramification types are $(2 A, 3,7)$ or $(2 A, 3,8)$. By Lemma 3.11.1 fixed point ratio of $2 A$ is $<\frac{1}{44}$, and fixed point ratios of elements $3,7,8$ are $<230$. Thus Lemma 2.5.20 suffices to rule out the Monster as a primitive low genus group.

## CHAPTER 4

## Braid Orbits on Nielsen Classes of

## Sporadic Simple Groups

In this chapter we provide a complete description of the braid orbits of low genus systems for the sporadic simple groups. A ramification type $\overline{\mathrm{C}}=\left(C_{1}, \ldots, C_{r}\right)$ of the group $G$ is said to be a Generating Type if there exists at least one generating tuple $\overline{\mathrm{g}}=\left(g_{1}, \ldots, g_{r}\right)$ of this type in $G$. In the previous chapter, we used several filters to eliminate most non- generating types and were left with a small collection of possible generating types of genus zero, one and two for each sporadic simple group. Consider a generating type $\overline{\mathrm{g}}$. Finding the braid orbits $O_{\overline{\mathrm{g}}}$ of the tuple $\overline{\mathrm{g}}$ is uncomplicated. Take a first random tuple $\bar{t}$ of type $\bar{g}$ and begin applying the generators of the braid group to $\bar{t}$ and then recording any new tuples in the list. Eventually we exhaust the orbit of $\overline{\mathrm{t}}$ and then we stop and record it. We repeat the same process for the next random tuple, and so on, until we find all the orbits. Note that the size of the braid orbits of the tuple $\bar{g}$ is dependent on the type length, that is, the longer the tuple then the sum of the sizes of (the braid orbit) increases dramatically, (roughly equal to $\alpha\left|g_{r}^{G}\right|$ where $\alpha \in(0,1)$ ). So computing a braid orbit corresponding to a long tuple may take long time. Firstly, we present tables listing the number of generating ramification types for each sporadic simple groups for which the corresponding Nielsen class is non-empty.

Table 4.1: Number of ramification types of the Mathieu groups which passed all filters

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $M_{11}$ | 47 | 95 | 149 | 291 |
| $M_{12}$ | 90 | 194 | 302 | 584 |
| $M_{12}: 2$ | 0 | 2 | 6 | 8 |
| $M_{22}$ | 24 | 38 | 46 | 108 |
| $M_{22}: 2$ | 52 | 111 | 152 | 315 |
| $M_{23}$ | 44 | 51 | 83 | 178 |
| $M_{24}$ | 115 | 231 | 288 | 634 |

Table 4.2: Number of ramification types of the Janko groups which passed all filters

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $J_{1}$ | 1 | 0 | 0 | 1 |
| $J_{2}$ | 2 | 3 | 4 | 9 |
| $J_{2}: 2$ | 2 | 7 | 4 | 13 |

Table 4.3: Number of ramification types which passed all filters

| Groups | genus zero | genus one | genus two | total |
| :---: | :---: | :---: | :---: | :---: |
| $H S$ | 0 | 2 | 7 | 9 |
| $H S: 2$ | 4 | 6 | 19 | 29 |
| $\mathrm{Co}_{3}$ | 1 | 0 | 0 | 1 |

Computing braid orbits on the Nielsen tuples of given type of length three is straightforward. Firstly define double cosets.

Definition 4.0.2. Let $H$ and $K$ be subgroup of the groups $G$ and $x \in G$. A double coset of $H$ and $K$ is the set

$$
H x K=\{h x k \mid h \in H, k \in K\} .
$$

Note that $H x K$ is the union of the K-orbits on its action on the cosets of H under right multiplication. Double cosets can be used to help us to find braid orbits for the tuples of length three. The next lemma provides us with more detail.

Lemma 4.0.3. Let $C=\left(C_{1}, C_{2}, C_{3}\right)$ be a ramification type of length three with class representatives $c_{1}, c_{2}$ and $c_{3}$. Then $\left\langle c_{1}, c_{2}^{k},\left(c_{1} c_{2}^{k}\right)^{-1}\right\rangle$ is the generating tuple of $C$ up to conjugation in $G$ where $k$ is in double $\operatorname{coset} C_{G}\left(c_{1}\right)-C_{G}\left(c_{2}\right)$ representative and $\left(c_{1} c_{2}^{k}\right)^{-1}$ in $C_{3}$.

Proof. Complete proof can be found in [37].

For the group $G$ the function Find3Tuple is defined in [37]. This function required two inputs which are the tuple(it should be of length three) and the group. If the type is a generating type then the output of this function is a list of Nielsen tuples of length one. Each tuple $\overline{\mathrm{g}}$ represents an equivalence class of covers of $\mathbb{P}^{1}$ with ramification type given by $\overline{\mathrm{g}}$.

### 4.1 MAPCLASS

MAPCLASS is a GAP package that is used for calculations of braid orbits and mapping class group orbits. MAPCLASS package has 17 functions. The primary functions of MAPCLASS are

- GeneratingMCOrbits(group,genus,tuple).
- AllMCOrbits(group,genus,tuple).
- GeneratinMCOrbitsCore(group,genus,tuple,partition,constant).
- AllMCOrbitsCore(group,genus,tuple,partition,constant).
- NumberGeneratingTuples(group,genus,tuple).
- TotalNumberTuples(group,genus,tuple).

In our work we used first and second above functions we will explain both of them.

### 4.1.1 GeneratingMCOrbits

GeneratingMCOrbits(group,genus,tuple) is the primary and most important function used in this computation. The objective of this function is to compute generating braid orbits on the Nielsen tuples of a given type. Note that this function calls a function NumberGeneratingTuples(group,genus,tuple) which finds the number of generating tuples. In this section we are going to explain how the orbits are calculated by the function GeneratingMCOrbits for a given group $G$, genus $g$, and ramification type $\overline{\mathrm{C}}=\left(C_{1}, \cdots, C_{r}\right)$. To achieve this, there are certain steps. The function first generates, for the type and genus, the action of the mapping class group generators. After that, it is calculating the total number of available tuples. This number allows us to know when we have already constructed all orbits. We require the knowledge of the variety of ways of achieving $\left[a_{1}, b_{1}\right] \ldots\left[a_{g}, b_{g}\right] c_{1} \ldots c_{r}$ for $a, b$ and $c$ in some finite group $G$, where $c_{i}$ is in the conjugacy class $C_{i}$. This scheme is achievable by taking the cardinality of the set of all homomorphisms from a Fuchsian group $\Upsilon=\left\langle a_{1}, b_{1}, \ldots, a_{g}, b_{g}, c_{1}, \cdots, c_{r}\right| \prod_{i=1}^{g}\left[a_{i}, b_{i}\right] \prod_{i=1}^{r} c_{i}=$ 1,$\rangle$ to the group $G$, which is denoted by $\Lambda\left(G, g: C_{1}, \ldots, C_{r}\right)$. Liebeck and Shalev[23]in Lemma

## 3.1, present an accurate calculation of this.

## Theorem 4.1.1.

$$
\Lambda\left(G, g: C_{1}, \ldots, C_{r}\right)=|G|^{2 g-1}\left|C_{1}\right| \cdots\left|C_{r}\right| \sum_{\chi \in \operatorname{Irr}(G)}\left(\chi(1)^{2-2 g-r}\left(\sum_{c_{i} \in C_{i}}^{r} \chi\left(c_{i}\right)\right)\right) .
$$

In particular, the number $\Lambda\left(G, g: C_{1}, \ldots, C_{r}\right)$ is exponential. The factor $|G|^{2 g-1}$ should be acknowledged as the most dominant term in the expression for $\Lambda\left(G, g: C_{1}, \ldots, C_{r}\right)$.

To find orbits, we choose a random tuple that has length of $2 g+r$ in which the elements of the positions $2 g+1, \ldots, 2 g+r$ correspond with our ramification types $C$ and hence the conjugacy class $C_{i}$ contains the $2 g+i$-th element. We are given access to new tuples as we successively apply generators of the mapping class group to a random chosen tuple. The already existing orbit is then compared with the new tuple. If a new tuple is not in the existing orbit then we add it. We then repeat this technique, taking tuples in our orbit, retrieved from the initial tuple. The orbit is then saved. All available tuples need to be considered, so we start taking random tuples that do not exist in our current orbits. It should be noted that the previous entire calculations were up to conjugation in $G$. A Minimization routine is used to check whether two tuples are conjugate or not. A limited explanation is going to be given but a more comprehensive one can be found in[19]. A tree diagram is the best way of representing the process of minimization and how it takes place. We suppose that the root of our tree is $(G, x)$ where $x$ is a minimal element of conjugacy class $C_{r}$. If $(K, y)$ is a node at the level $n-1$ of our tree, the children of $(K, y)$ would be pairs of the form $\left(C_{K}(y), m_{i}\right)$. Here $m_{i}$ is is considered as the minimal element of the orbits of $\left(C_{K}(x)\right)$ in the conjugacy class $C_{n}$. For each conjugacy class, the minimal elements that belong to the same orbit can be tracked. Until all the $K$ are trivial or all conjugacy class are resolved, we proceed with a continuous system. Hence the tuple $g=\left(g_{1}, \ldots, g_{r}\right)$. The minimization system works in the following manner: for every $g_{i}$, a corresponding minimal element $m_{i}$ is chosen from the tree. All of the $g$ is then conjugated with $k_{i} \in K$ and hence taking $g_{i}$ to $m_{i}$ and then repeating the process with a new tuple. Elements that were previously chosen for the process of minimization will be fixed by further conjugation as we'll be conjugating by an element contained in the intersection of centralizers.

As we have seen this function require three inputs which are the group, the genus and the tuple. The tuple is a tuple of conjugacy class representatives of the given group. Although the number of orbits, length of orbits and size of centralizer etc. are outputs of this function, our requirements are the number of orbits and length of orbits. Now we give an example of a sample run of this function.

Example 4.1.2. Let $G$ be the Mathieu group $M_{11}$. For genus two in the first class of maximal subgroup there is a tuple $(2 A, 2 A, 2 A, 2 A, 5 A)$ of length five. The

```
tuple :=[ ( 3, 7)( 4,11)( 5, 9)( 6, 8), ( 1,10)( 2, 4)( 3, 5)( 8, 9), ( 1,
6)( 2, 4)( 5, 9)( 7,10), ( 2, 8)( 3, 4)( 5, 9)( 6,10), ( 1, 8, 2, 5, 7)( 3,11,
4, 9, 6)] is of type (2A,2A,2A,2A,5A).
gap> GeneratingMCOrbits(G,0,Type);;
gap> Length(last);
gap>1
gap>orb:=orbits[1];;
gap>Length(orb.TableTuple);
gap>12000
```

We see that in this case the braid group has exactly one orbit of length 12000 on the Nielsen class $(2 A, 2 A, 2 A, 2 A, 5 A)$. So for the tuple of long length in large groups the problem such of computing the braid orbits requires a computer with large memory and such computer may not be available. We then used the function AllMCOrbits(Group,genus,type) we will explain in next section. Now in Table 4.4 we collect the data for our calculations of braid orbits for groups of the tuples of length $\geqslant 4$.

Table 4.4: Generating braid orbits for types of length $\geqslant 4$

| Groups | RamificationTypes | N.Orbits | LengthOfOrbits |
| :---: | :---: | :---: | :---: |
| $M_{11}$ | ( $2 A, 2 A, 2 A, 2 A, 3 A)$ | 1 | 2376 |
|  | (2A, 2A, 2A, 2A, 2A, 2A) | 1 | 229680 |
|  | $(2 A, 2 A, 2 A, 2 A, 5 A)$ | 1 | 12000 |
|  | ( $2 A, 2 A, 2 A, 2 A, 3 A$ ) | 1 | 2376 |
|  | ( $2 A, 2 A, 2 A, 2 A, 6 A$ ) | 1 | 12528 |

|  | $(2 A, 2 A, 2 A, 2 A, 5 A)$ | 1 | 342600 |

### 4.1.2 AllMCOrbits

Both generating braid orbits and non-generating braid orbits of the given groups are computed by this function. For the large groups or for the long tuples the function GeneratingMCOrbits does not work. For instance the braid orbits of the ramification types in Table 4.4 for the group $M_{24}$ can not be found by the function GeneratingMCOrbits. Using this function is quite easy but the long time is required to compute it. Moreover we have to use several steps to find generating braid orbits. This function requires three inputs which are the group, the genus and the tuple. The number of all orbits, length of orbits and size of centralizer etc. are outputs of this function, our requirement are the number of generating orbits and length of generating orbits.

```
AllMCOrbits(group,genus,tuple)
```

The following example demonstrates how one can find generating braid orbits.
Example 4.1.3. Let $G$ be the smallest Mathieu group $M_{11}$ and $g=2$. The tuple $=[(2,10)(3,4)(6,8)(7,11),(2,8,10,6)(3,7,4,11),(1,2,7)(3,8,4)(9,10,11)$, $(2,7,6,3,10,11,8,4)(5,9)]$
is of type $(2 A, 3 A, 4 A, 8 A)$. Recall that a ramification type $\overline{\mathrm{C}}=\left(C_{1}, \ldots, C_{r}\right)$ of the group $G$ is said to be of generating type if there exists at least one generating tuple $\overline{\mathrm{g}}=\left(g_{1}, \ldots, g_{r}\right)$ of this group. In the other words a ramification type $\overline{\mathrm{C}}=(2 A, 3 A, 4 A, 8 A)$ the will be of generating type if there exists a braid orbit $O$ such that the tuple from it generates sporadic the simple group $G$.

```
gap> AllPrimitiveGroups(DegreeOperation,11);;
```

gap $>\mathrm{G}:=$ last [6] ;
M(11)
gap $>0:=A l l M C O r b i t s(G, 0$, tuple) ;
gap> Length(0);

4
gap $>$ for i in [1..Length(0)]do
$>$ Print(Length(0[i].TupleTable));
> Print(" $\backslash \mathrm{n} ")$;
>fi;od;
951
225
12
6

The above program shows that there are four braid orbits of length $951,225,12,6$. Now for each braid orbit we look for a group $K$ generated by the tuple from the orbit $O$. Firstly we have to check that whether $K$ is a primitive group.

```
gap>for i in [1..Length(0)]do
>h:=Group(O[i].TupleTable[1].tuple); >if Isprimitive(h)=true then ;
> Print(i);
> Print("\n");
```

$>f i ;$
>od;
1
2
It should be noted that the first tuple from orbits one and two generate primitive groups. On the other hand the first tuple of the orbit three and four does not generate the primitive group. Next we check that the size of primitive groups is equal to the Mathieu group $M_{11}$.
gap> A:=AllPrimitiveGroups(DegreeOperation,11);
$[C(11), D(2 * 11), 11: 5, \operatorname{AGL}(1,11), L(2,11), M(11), A(11), S(11)]$
gap> h1:=Group(0[1].TupleTable[1].tuple); ;
gap $>$ for $i$ in $[1 . . \operatorname{Length(A)]do~if~} \operatorname{size(A[i])=Size(h)~then~;~}$
$>\operatorname{Print}(i) ;$
> Print(" n ") ;
>fi;
>od;

6
gap $>$ IsomorphismGroups(h1, A [6]) ;
$[(2,3)(5,11)(7,8)(9,10),(1,3,6,5)(4,9,7,11)]->[(2,3)(4,11)(5,6)(7,10)$, $(1,3,6,4)(8,11,9,10)]$

This means that the first tuple from orbit one generates a primitive group which isomorphic to the smallest Mathieu group $M_{11}$.

```
h2:=Group(0[2].TupleTable[1].tuple);;
```

gap>for i in [1..Length(A)]do if size(A[i])=Size(h) then ;
> Print(i);
> Print(" $\backslash \mathrm{n}$ ");
>fi;od;

So the first tuple from orbit two generates a primitive group which is not isomorphic to the group $M_{11}$. Hence we ignore this primitive group. Thus the ramification type $\overline{\mathrm{C}}=(2 A, 3 A, 4 A, 8 A)$ has one braid orbit of length 951.

## CHAPTER 5

## Conclusions

This thesis set out to calculate the connected components of $H^{i n}(G, C)$ where $G$ is a sporadic simple group. The total numbers of components of $H^{\text {in }}(G, C)$ are shown in the Tables

In fact to establish this result, firstly in Chapter 2 and the first section of Chapter 3, we presented some filters to eliminate non generating ramification types of sporadic simple groups. Moreover, we proved Lemma 2.5.18, Lemma 2.5.19 and Lemma2.5.20, that play an important role in eliminating ramification types of large sporadic simple groups. In Chapter 3 we check whether or not the sporadic simple groups possessed primitive genus g systems by using filters. For large sporadic simple groups, we found fixed point ratios and, by using Lemma 2.5.19, we showed that these groups possessed no primitive genus g-system. Note that the GAP library stores primitive permutation groups up to degree 2500 . In some cases where the group possesses
a permutation representation of degree $<2500$, we were able to construct explicitly all the permutation representations of degree $>2500$ that we needed to work with .

Secondly, we computed braid orbits of the sporadic simple groups that possess primitive genus g-systems by using the packages Braid and MapClass. However, in one case, namely $(2 A, 2 A, 2 A, 2 A, 2 A, 2 A)$ for the large Mathieu group $M_{24}$, we were not able to compute all braid orbit because its Nielsen class is too big. We leave this case open but suspect that there is only one braid orbit of this type of length 12307440 . We hope to be able to address it in our future work. In this thesis we compute braid orbits of Nielsen Class of sporadic simple groups, future work we will compute the braid orbits of Nielsen class of low genus systems for other almost simple groups (Classical groups).

## Appendix A

## GENUS ZERO COVERS

Appendix A contains table representing the result of our computation of primitive genus zero cover in sporadic simple groups satisfying Theorem 1.0.2. Note that N.Orbit means number of orbits, L.O means length of orbits.

## Appendix B

## GENUS ONE COVERS

Appendix B contains table representing the result of our computation of primitive genus one cover in sporadic simple groups satisfying Theorem 1.0.2. Note that N.Orbit means number of orbits, L.O means length of orbits.

## Appendix C

## GENUS TWO COVERS

Appendix C contains table representing the result of our computation of primitive genus two cover in sporadic simple groups satisfying Theorem 1.0.2. Note that N.Orbit means number of orbits, L.O means length of orbits.
